In the *Archives de Médecine Navale* for May, 1895, is noted a report on the fevers of Massowah undertaken by medical officers of the Italian Navy, who found three different fevers: (1) Malaria cases, imported only; (2) an indefinite fever, no germ isolated; and (3) typhoid: (*a*) abortive—*Bacillus typhosus* in blood from finger; (*b*) developed. That reported from the *Euryalus* at Massowah in 1884 may perhaps be included in their No. 2. I was in those days serving at Zanzibar in the *Swallow* sloop, and we tried to get her thoroughly aired—windsail in every hatch and windscoop in every scuttle; we all felt this did us good. The old proverb is that a smart ship is a healthy ship, and she was pretty busy as well as pretty that *Swallow*, but I regret that I cannot give statistical evidence of her health. We got a great deal of malaria when landed, but we thought we did not have so many fever cases as usual. The lesson of these East Coast fevers may be thus stated. 1. The importance of accurate diagnosis; no prevention of the ship fever could be other than blind so long as it was supposed due to malaria or climate which you could not change. If we had dreamed it was due to stuffiness of the ship, I am sure the captain would have had the men sleeping away in boats or going route marches to let the ship dry, or something would have gone on being done till the right thing was found. 2. The importance of not being led astray by popular etiology. 3. The little direct influence on disease of that resultant of meteorological conditions called climate.

I must now ask you to consider another example of inaccurate diagnosis which also hindered prophylaxis and did much more harm, as there were far more people concerned. I now refer to what we called Malta fever. When I entered the service in 1885 the crux of the Naval Medical Department was, as we who then entered very soon learned, Malta fever—a great many cases for which we had no satisfactory treatment, with many invalidings though few deaths. No prophylaxis could be hopefully considered, for the disease we knew was due to the climate of Malta, which we could not alter, and, besides (here came in the mischief of faulty diagnosis), it attacked the soldiers as well as us. This fever was not described in the text-books; there was no book about it; we believed the people who had seen much of it knew something about it, but it was surprising how little they could tell us. In January, 1886, I was told off to the *Alexandra* in the Mediterranean, and naturally searched for all the information I could get. The most weighty came from the Inspector-General at Haslar, who had had long experience of the Mediterranean, and he kindly talked to me about this fever, concluding by advising me to keep a great-coat in our mess boat to protect me in going off to the ship at night. In fact, the only prophylactic then known was—avoid chill. We of the new ship's company for the *Alexandra* were sent to her from Portsmouth on Feb. 20th in H.M.S. *Tamar*. Reaching Malta on March 1st we were turned over to H.M.S. *Hibernia* for two months until the *Alexandra* had refitted. The *Tamar* was crowded, and in our own ship's company we had a dozen cases of pyrexia, indistinct at first, but later becoming pneumonia or bronchitis, and similar cases continued to occur after we left her until the end of April, when these cases were replaced by others called fever.

Marston[2] in 1860 wrote a paper on fevers at Malta, which appeared in 1863 in the Army Medical Department Report for 1861. He classified them as simple continued, typhoid, and gastric remittent. This classification practically it was that was followed in our returns in 1886. The simple continued fevers were the slight cases. Some medical officers there were who thought this a definite disease like typhoid. Others thought it a limbo for slight cases of fever due to undiscriminated infections; all slight cases of remittent and abortive attacks of typhoid, for example, fell into this group.[3] The prolonged and more serious cases were divided between typhoid and remittent. Those with more definite abdominal symptoms, diarrhœa, three weeks' pyrexia, and then lysis, and especially if they had a fatal issue, would be called typhoid, particularly if rose spots had been seen or a post-mortem examination had shown the ulcerated Peyer's patches. The rest that could not be called typhoid would be classed as remittent, and were of all degrees of severity, from the uncertain week-long pyrexia, which would have been called simple continued had not the temperature been so high and the symptoms so severe, to the well-developed case one sometimes saw with a prolonged weary clinical course without strongly marked features but going on relapsing, sometimes with well-marked rheumatic sequelæ (this I used specially to note in cases seen in the military hospitals), and a death-rate of 2 per cent. Except the typhoid, we thought all these fever cases to be the same and peculiar to the island. They were returned as remittent, but in conversation we called them Malta fever. Our attention was rather focussed on the bad cases, of which I saw a good many in my first week at Malta, when sent to do duty in the Naval Hospital and later at the Valetta Hospital, where was living Sir David Bruce, who showed me more.

---

[2] I have not emphasised Surgeon-General Marston's work but in my mind it was obviously all-overshadowing. He discriminated in 1860 the Malta fever of Bruce from typhoid fever at a time when clinical methods only were available and so prepared the clinical grouping which made Bruce's work possible in 1886.

[3] Simple continued fever is by many [illegible] to be abortive [illegible] typhoid. It is reported, however, by Surge[illegible] of the *Powerful's* landing party of 250 men who [illegible] the Ladysmith suffered from this fever equally whether below or above the age of 25 years. This is quite a different age-incidence from that of enteric fever (Blue-book "Navy Health," 1899, Appendix).

We were then at Malta seeing a quantity of fever cases really undistinguished except by severity between slight febricula and a four or five months case of Malta fever, so I think there is a little excuse for us that we did not realise that they ought to be broken up into groups. Another difficulty I will tell you in a minute. None of us knew how these cases came, but the most frequent hypothesis was dirt. Bruce talked of soil saturated with the filth of centuries. [illegible]

Thinking it over again now, I feel that the army had more "rheumatism" as a sequela to their "fever" than fell to the cases in the service afloat. I did notice then that young soldiers one used to go and see at Cottonera Hospital had a rheumatism following fever much more crippling than that which our patients experienced. Here was the hint of a discovery which, alas! I did not make in time. What masked this observation, what gave our people rheumatism as a sequela, was that cases sent to our hospital sometimes got fever there (popular lay opinion said every case) from the milk—as we now know, but did not then,—and these cases might very well develop rheumatism even if none had it in ships from their primary infection. Then cases were called remittent fever which obviously were not so. I remember *Inspector-General Todd, then senior surgeon in the Alexandra*, showing me that a pyrexial case which I thought to have intractable Malta fever was really suffering from inflammatory fever and was at once cured by the opening of an abscess, and there were other people then just as young as I.

In 1891 I was sent to do duty at the Admiralty for a fortnight, and, having access to records, read up many reports on this fever, and that winter at Inverness, in medical charge of but a small ship's company, had time to write a report on Malta fever for the journal we send into office every year. This report, amplified, became, in 1895, my thesis for the degree of M.D. in Edinburgh. In that thesis I tried to [illegible], that Malta [illegible] be prevented [illegible] nvestigation seemed to lead to this same conclusion that I was confident this investigation of mine was sound. When, therefore, the Malta Fever Commission was being appointed I sent Bruce a copy of that thesis to help them. He said he would lay it before them, but indicated that in his opinion it would not advance them much. In 1906 Bruce's Commission had stopped Malta fever, and I found the surgeon I had got in H.M.S. [illegible] *read it, indeed, but to my vexation he, too, said it was of no* particular interest, adding that these older papers were quite unimportant now and gave no enlightenment, since the cases on which they were based could not—it was not possible they could—have been accurately diagnosed in those days.

I may explain here, as some members *may not remember* the dates, that in 1886 Bruce found in the spleen of fatal cases of Malta fever a micrococcus, the *Micrococcus melitensis* as it is now called, and by inoculating this into a monkey he proved it to be the cause of the disease. Several of us then went about pointing out the great cleverness of the medical profession which could find the cause of a disease so troublesome. We were, however, only met by our lay friends with biting remarks about the uselessness of knowledge of a disease which did nothing to help its cure, and our arguments that advances in knowledge were valuable in themselves had few takers. However, Bruce's discovery had, at least, made the accurate diagnosis of this disease possible in the post-mortem room, which was something, though otherwise it seemed to have been of no practical benefit, and so things remained for 10 years, until the Widal reaction was discovered. *Sir Almroth Wright soon noted that the serum of Malta fever cases clumped its bacillus alive or dead.* In about three years this reaction became generally used in Malta. Bruce's discovery had now led to the diagnosis of cases during life, but had certainly not yet improved treatment. In 10 years more we find the Commission hunting all over Malta for this micrococcus, finding it in goats, then in their milk, and so, in July, 1906, this fever was stopped, and there practically has been none since in the army or the navy. And it is better to prevent a man from wanting treatment for a disease than to give him, sick, the best treatment. Does not this all show that it is worth while to obtain any increase in knowledge, for trifling as it may appear at first there is no knowing how far-reaching it may prove; 1886: micrococcus found and diagnosis possible in post-mortem room; 10 years on (1897 to 1900): serum reaction and diagnosis made possible of cases *during life; 20 years after* (1906): fever stopped and no diagnosis required any longer. The history of the prevention of this fever is particularly interesting. It was so restricted in area and with so little to differentiate it in life from other fevers, that one cannot see how it was to be investigated unless Bruce had found the micrococcus—a specially hard nut for us of this society, who, when we hear of a disease, think of it as something to be prevented. How long would it have been before someone thought it worth while to trace the effect on each of the consumers during a month of the milk of each of a flock of 20 apparently quite healthy goats? Beside such a toilsome research, even Dr. Davies's patient and skilful unravelling (in Vol. XVII. of the Transactions of the Epidemiological Society) of the milk routes by which typhoid came to Clifton seems quite easy.

I will now go back to Surgeon Richards's opinion on my thesis. It was quite clear that he was correct; that thesis of mine did seem valueless. Malta fever was due to a specific *infection of goats' milk. Whatever could I have meant by* alleging it was due to faulty ventilation and overcrowding? Another thing puzzled me much. What were we in the service afloat doing with all that Malta fever from infected milk, when I suppose no milk was drunk on board ship except by the officers' messes and by their servants? The men never drank milk to my knowledge unless they were on the sick mess. Where did they get the fever?

In writing the results of overcrowding for a section of a book on naval hygiene which I was planning I recognised that the Malta fever of which I had written in my thesis was one of these diseases of overcrowding, and then became sure that in Malta, about 1886, there were at least two fevers unknown to the text-books of that day—one *Micrococcus melitensis septicæmia* of Bruce, due to infected milk, which specially attacked (1) people ashore, (2) the army, and (3) patients of the service afloat who got milk in sick bays or in hospital. This, by much the more important of the two, is the fever commonly known as Malta fever. The other fever which also occurred mainly, though perhaps not *exclusively, at Malta*, was a fever of overcrowded ships, attacking, so far as we yet know, only the navy, and of them only the crews of certain ships. This fever has since gradually decreased, till now the structure, management, and equipment of ships have so improved that one hears this fever has completely disappeared. *Bruce concerned himself only with the first; I concerned* myself only with the second. Again the case of opposite sides of the shield.

And now I must try to show you that some cases were due to overcrowding. You might think that overcrowding could *not but be recognised* and rectified. To prove how much overcrowded a ship could be without people clearly recognising that it was so I would quote a paper read to this society in 1863 by Dr. Smart, then an Inspector-General, on epidemic pleuro-pneumonia in the Mediterranean in 1860. The *St. Jean d'Acre* was commissioned in 1859, and by the end of June had *reached the Mediterranean. She was* considered overcrowded. The ship's company, 850 of them, slept in hammocks on the lower deck, each man having only 28 inches laterally, so that in harbour they formed, as the doctor, Edmonds, said, a compact mass. He notes that on April 8th the temperature of the air below the hammocks was 60° F., while that above was 81°. So considerable a difference produced strong draughts, which led the people near the ports to close them and thus made the ventilation worse. The lower deck is also reported as too damp *from* over-frequent washing. 153 cases of fever were sent to hospital in her first six months at Malta—continued fever, tending to become "remittent, many assuming a typhoid character." In fact, exactly like ours of 1886-89. She was sent to Corfu and improved in health, but returning to Malta three months later became, as the old word was, "sickly" again at once; in the succeeding nine months, though the overcrowding of the lower deck was a little reduced, 100 men being taken off it, there were noted these cases:—

Bronchitis	7	Pleurodynia	20
Pleuritis	19	Cachexia pulmonum (slight cases suggesting phthisis)	117
Pneumonia	13		
Hæmoptysis...	7		
Phthisis	102	Total	285

Things were not quite so bad as this suggests, for many of the cases were subsequently decided not to be phthisis, though they resembled it. But six cases did die. It is said that some new class of recruits had been taken in the ship, subjected to medical inspection less rigorous than usual, so I suggest that she was suffering from overcrowding with a considerable phthisical infection larger than usual. Overcrowding was indeed thought possibly a cause, but it was not definitely decided to be the cause. Decaying wood and foul bilges were also held to blame. No one was convinced that overcrowding was the cause. One wonders why all these men were put to sleep on the lower deck when there were two other decks higher up, and with better ventilation, almost untenanted. I expect this was a legacy from the great war and done to leave the guns on those other decks unencumbered in case of a night attack.

Now to take examples of this remittent fever in the Mediterranean, consider the *Royal Oak* in 1866. In previous years she had suffered much from fever and was now in June at Malta, and frequently sending cases of fever to hospital. "On June 18th the lower deck was relieved of 130 men, and from that time a decided improvement set in." At the same time the ventilation of the lower deck was much improved, and at the end of September the sick list was half that of the previous year. The sick rate, which had always previously increased in the third quarter, now fell off, and that for the Christmas quarter was the lowest hitherto in the whole commission of the ship.

In the "eighties" fever is frequently reported from the Mediterranean, and the annual reports generally state the *number of cases in the ship that suffered most.* These below are the big ships:—

Year.	Ship.	Cases.	Percentage of complement.
1882	*Monarch*	149	30
1882	*Superb*	136	20
1883	*Inflexible*	29	6
1884	*Superb*	124	20*
1884	*Alexandra*	82	12
1885	*Alexandra*	83	12
1885	*Téméraire*	60	10
1886	*Alexandra*	64	10
1887	*Alexandra*	70	10
1887	*Dreadnought*	11	2½
1889	*Dreadnought*	13	3
1890	*Agamemnon*	39	10

* Specially noted as due to Malta

It is to be presumed that those not mentioned suffered less. Now anyone acquainted with these ships will divide them at once into two groups:—

(1) Incidence 30 to 10 per cent.	Per cent.	(2) Incidence 10 to 2½ per cent.	Per cent.
Monarch	30	*Inflexible*	6
Superb	20	*Dreadnought* ...	3 to 2½
Alexandra	12 to 10	*Agamemnon*	10
Téméraire	10		

No. 1, with higher incidence, are called central battery ships. They have hand-worked guns and large complements of men required to work them and smaller space per man. No. 2, turret ships with few and power-worked guns, small complements, and more room, had small incidence. I will compare two of them in which I had the good luck to serve—*Alexandra* and *Dreadnought*.

	Alexandra.	*Dreadnought.*
Displacement	9800 tons	10,000 tons
Guns	12	4
Complement	750	450
Tons per man	13	22

The *Alexandra's* men were carried on three decks, so you can easily see that those sleeping below must have had less air than the men had in the *Dreadnought*, where very few were on a second deck, and those had artificial ventilation. The *Dreadnought* was much drier than the *Alexandra*. When I went to her I took over some clothes that in my cabin in the *Alexandra* were threatened with mildew, and this in my lower deck cabin in the *Dreadnought* was killed by the warm dry atmosphere.

We had a very interesting experience in the *Alexandra* in 1886-89. She was kept throughout the commission as clean and dry as possible. Her first lieutenant (now Admiral), F. S. Inglefield, painted the "flats" or lower deck white to show up the dirt. These flats were washed once a week with warm fresh water and carefully dried up immediately after; a deck-cloth was then put down, and this was sent ashore at the end of the next week to be washed to save dampness on board. For the first two years she was only cleaned by candle light, and in each year you see she had 10 per cent. of the men attacked with fever. Before the third year the ship was fitted with electric light, and now not only could a higher standard of cleanliness be attained but there was less damp and dirt from the burning candles. A boiler was always alight to run the dynamo, and what with the furnace drawing part of its air from the flats and so improving the ventilation, and what with the heating of the ship by conduction from that boiler, the flats became beautifully sweet, clean, and dry; the micro-organisms that used to grow there were removed or killed, we had only 3½ per cent. of the men this year down with fever, and we were no longer pilloried in the Blue-book. It is unsafe to over-minutely compare two *years with one another, for one does not know quite how* much time was spent at Malta, and it was at Malta that the ship suffered from this fever.

It is difficult to assign exactly the importance of humidity in the factors of health; it comes in in part directly as favouring the growth of micro-organisms, in part indirectly as a measure of insufficient ventilation. In my early days I thought that humidity must have great importance as a cause of disease, and in my journal for 1888 I was able to put in a note showing on two years' observations that in the *Alexandra*, with 700 men, at Malta in the winter, there was always a case of sore-throat at the morning visit if there had been recorded during the previous 24 hours a humidity of or above 80 per cent.[3] I thought then that the relation was direct, but the high percentage humidity was certainly an evidence of still weather in which ventilation was at its worst. There was a popular belief in the fleet that the fever was more frequent in still weather.

The experiences of H.M.S. *Trafalgar* in 1891 and 1892 are of great interest. She was a turret ship, but of a new pattern, with a secondary battery, the men, consequently, being more shut in than in the *Dreadnought*. The *Trafalgar* was in Malta Harbour near or in dry dock from Feb. 10th to May 5th, 1891, and returns 159 cases of continued fever, 85 of remittent, and 24 of enteric from a complement of 600 men. The fever rapidly increased from the beginning of April. The next year she was to spend the same period in dockyard hands, but a definite effort was made that there should be no fever this year. Windsails were hoisted everywhere possible, every attempt was made to secure cleanliness, dryness, and thorough ventilation of the ship. Also the men were daily landed by watches and sent to Corradino Parade Ground to air them and give the ship a better chance to dry, and while they were in dry dock this year no fever cases occurred.

But if this fever is only due to overcrowding in a ship why should it have been called Malta fever? It has, in fact, been reported from elsewhere, as, for example, from the Channel Fleet in 1884, where Inspector-General (then Fleet-Surgeon) G. Maclean, who afterwards came to the *Alexandra*, drew attention to the number of pyrexial cases which came on the list as soon as ships went to sea and had to close their ports and spoil their ventilation, and he notes how closely the cases that then present themselves resemble those known in the Mediterranean as Malta fever. These cases were more frequent at Malta than elsewhere. Why? There are three reasons:—

---

[3] Having obtained statistical evidence of a relation between humidity and the occurrence of cases of disease, I was anxious to find other
I first.
For some years I sought in vain.
about 1780, quoted by him from a thesis,
ke mine submitted to the University of
I.D., but about 1750, and by my great-
ready mentioned. He afterwards became
and President of the Royal College of
posed to be the first person to describe
diphtheria; he called it croup. (See Löffler in Nuttall and Graham Smith's "Diphtheria.")

1. The biggest ships of the navy, those with largest complements, were at Malta, and it was generally numbers of cases, not percentages, that were reported and impressed people. The big ships of those days were only in the Channel and Mediterranean, and having only natural ventilation were always worse off than the small craft, the mess decks of which are quite close to the outer air.

2. The temperature at Malta was such that the ventilation of these large ships was there at its worst. When air is breathed it is heated, it is also made moister, and by each of these changes its specific gravity is lowered—that is, the expired air is lightened and these changes make it rise away from us. But it also has its lighter oxygen replaced by heavier carbonic acid, which tends to make it denser. The ultimate specific gravity of the expired air is the resultant of all these changes and varies at different temperatures. Dr. Shaw, director of the Meteorological Office, in his recent most valuable book, "Air Currents and the Laws of Ventilation," has calculated 81° F. as the temperature about which these processes balance one another, so that the difference between the specific gravity of inspired and expired air vanishes. As he says: "At such a temperature a crowd would inevitably be poisoned by its own breath." Now you may remember that 81° F. was the temperature of the air which Dr. Edmonds at Malta found the tars breathing in the *St. Jean d'Aro* during her great epidemic.

3. The physical conformation of Malta Harbour, so different from that of any other harbour with which I am acquainted, also helped to spoil the ventilation of the ships by keeping off them any possible breeze there might be. The Grand Harbour at Malta is wonderfully convenient for seamen. There is quite deep water close alongside, and I doubt whether ships of the deepest draught are anywhere else in the world so closely packed together, and as the water close alongside the shore is so deep ships are able to lie just under the high fortifications, another most unusual feature of this harbour. These great high walls shut off from the ships any little breeze there may be which might give us a little change of air on board in a warm night.

A study of the Blue-books will, I think, convince anyone that the incidence of "fever" was greatest on ships lying at the top of Dockyard and French Creeks and in the dry docks. Such was the experience, anyhow, of the *Enterprise* in 1866, *Monarch* and *Condor* in 1882, *Superb*, *Iris*, and *Carysfort* in 1884, *Agamemnon* and *Polyphemus* in 1887, and *Trafalgar* in 1891. In 1887 *Carysfort*, doing same work as in 1884, refitting in the summer, escaped fever because, as I think, the cholera scare of that year sent her out to Bighi Bay to lie, very inconvenient for her work and costly to the country, a cause probably too of great vexation to her people, but at the same time salutary. [illegible] Besides, [illegible] been [illegible] *Trafalgar*, in 1863, lost the fever when moved from French Creek to Bighi Bay, as did the *Enterprise* in 1886 when moved round to Sliema. A move of this sort seems generally to have done good, perhaps, of course, because it would not be mentioned unless benefit had accrued. And a move of this sort seems to do more good than a trip to sea, for the move to sea may be made in bad weather when the ports are closed and ventilation the more diminished. To return to the instructive vicissitudes of the *Alexandra*; in June, 1887, she had much fever, and leaving Malta we cruised up the Italian coast, but we did not begin to lose it, nor the patients to thoroughly and clearly improve till we got to Golfo d'Aranci in the N.E. corner of Sardinia, where a strong breeze (force 4 to 5) blew through the ship every afternoon.

What I hope you now recognise with me I may shortly state: that in Malta, 1886-89, there were two fevers unknown to the text-books—one, Bruce's *Micrococcus melitensis septicæmia*, commonly called Malta fever, attacking people who lived on shore, or drank milk, included amongst these last being patients sent to hospital from the service afloat; the [illegible] ack- [illegible] but [illegible] ying [illegible] rous temperature, a numerous fleet of our largest ships. Bruce was then concerning himself with his fever only, I specially with ours, while Gipps, working with Bruce at bacteriology, was involved with both. It is distressing to think how much good Gipps and I might have done at that day in earlier prevention if we had not fixed our attention so much on the stagnant filthy water of the harbour and had given more thought to the harbour air. I have taken up your time for too long. In conclusion, I would like to tell you that the management, equipment, and construction of ships have so much improved that this fever of overcrowding is not likely to recur in any considerable degree, even in Malta. The improvement in the health of the service is manifest. This society will readily, I suppose, accept phthisis as a measure of the degree of overcrowding. In the *Alexandra*, 1886-89, we had, per 1000 men per annum, eight cases of phthisis; in the *Galatea*, in Home Fleet, 1901-02, six cases; and in the *Exmouth*, 1905-07, the score had gone down to two. I am sorry I cannot tell you the sick list of the Mediterranean Fleet, but in 1901-02, in Home Fleet, the number generally off duty sick and in hospital was 4 per cent., but a new class of ships then came in, and in the Channel Fleet, 1905-07, the *Exmouth*, with flag of Sir Arthur Wilson, being flagship, the average percentage sick and in hospital was only two, and this, in the same climate, halved in four years. The *Exmouth* class had larger cubic space and corticine on the decks. They were the last class without artificial ventilation for the mess decks. So I expect that in new fleets of newer ships you will soon hear of still further marked reductions.

NOTES ON A FATAL CASE OF SPLENOMEGALIC POLYCYTHÆMIA (ERYTHRÆMIA).

BY WILLIAM F. UMNEY, M.D. LOND.,
PHYSICIAN TO THE HOSPITAL FOR CHILDREN, LOWER SYDENHAM;
LATE HOUSE PHYSICIAN, ST. THOMAS'S HOSPITAL, ETC.

SOME few cases of this "new disease" have been recorded lately, and a very full and descriptive account of it was given by Professor W. Osler in THE LANCET of Jan. 18th, 1908 (p. 143). In the following case the cardinal symptoms of the disease were exhibited in the most marked manner; but the complications of chorea and general thrombosis, which brought about a fatal termination, have not, as far as I know, been noticed before, and I venture to think, therefore, that they are worthy of record. In a considerable number of the cases cerebral hæmorrhage appears to have been the cause of death.

The patient, a married woman, aged 34 years, first came under my care in October, 1905. She had been seen a few times by my locum-tenent, whilst I was away on my summer holiday, for what she thought was a miscarriage, but which was evidently only a rather profuse period after an absence of menstruation for about four months. When I saw her this had ceased, but I found hæmaturia, which lasted a few days and was followed by permanent albuminuria. The patient was a thin, wiry woman of a nervous temperament, bright, cheerful, and very active, and she expressed herself as feeling perfectly well. There was nothing of much note in the family history, except that all were "nervous" and that one brother had died young from phthisis. The patient herself had only suffered from the ordinary diseases of childhood. She had never had rheumatic fever, or any other form of rheumatism, chorea, or attacks of tonsillitis. As a girl she had suffered from anæmia. She had never been abroad and there was no history or suspicion of syphilis. She was married in 1900 and lived in the Midlands. Soon after her marriage she began to notice a bluish colour in her complexion; this had gradually become intensified and was [illegible] in cold weather. It had not in any [illegible] lth, but it had led to remarks by [illegible] to her being stared at in the [illegible] considerable annoyance. Before marriage her menses were rather irregular and they continued so afterwards. In August, 1902, she had a miscarriage, being about four months pregnant. From this time menstruation was [illegible] more irr[illegible], sometimes being absent fo[illegible] and she had seen [illegible] hen I first saw her [illegible] May, [illegible]).

On examination I found no signs of disease in the heart or lungs; the liver was not felt, but the spleen was considerably enlarged and extended three or four fingers' breadth below the ribs; it was not tender on pressure. The kidneys were easily palpated; they were somewhat moveable and distinctly enlarged. A specimen of urine was sent to the Clinical Research Association and the following report was received: "Sp. gr. 1013; albumin present in considerable amount; a few granular tube casts and red blood discs present. There is evidence of nephritis, suggesting that the hæmorrhage has been associated with some renal condition." The radial arteries were considerably thickened but not tortuous and could be rolled under the fingers. The pulse was regular, about 96 per minute, and very tense. The whole body was of a remarkable colour. The cheeks, nose, lips, ears, and fingers were bluish-red, and the skin of the chest, back, and abdomen was of a uniform deep-red hue. The palms of the hands were also quite red. There was no clubbing of the fingers. Tiny venules were noticeable on the cheeks and the conjunctivæ were suffused. The whole appearance was novel and startling, quite different from anything I had ever seen before. I at first thought I had a case of chronic nephritis with unusual symptoms of cyanosis to deal with, but soon came to the conclusion that such was not a satisfactory diagnosis.

At the end of November, 1905, I sent a specimen of blood for a count of the corpuscles to the Clinical Research Association, and received a note saying that the specimen was useless for examination, as it had not been accurately diluted. A second specimen was sent, and the average of two counts gave the following results: red cells, 9,400,000 per cubic millimetre, and white cells 8400 per cubic millimetre. A note was added saying that "These figures agreed sufficiently closely to prove no mistake had been made in the first count, and that they had not before seen such extreme plethora, but that figures little short of the above had been found by Cabot of Boston in two cases, in which the only signs were cyanosis without evident cause." A few weeks later my friend, Dr. J. J. Douglas of Upper Norwood, kindly saw the case with me and examined the blood. His figures were even higher—viz., red cells (which looked normal), 11,500,000 per cubic millimetre; white cells, 17,000 per cubic millimetre; hæmoglobin, 138 per cent.; colour index, 0·6; proportion of red to white cells 640 to 1. The blood was extremely dark in colour, viscid, and coagulated very quickly.

I now recognised that the patient was suffering from polycythæmia, associated with enlargement of the spleen and cyanosis, and she was allowed to lead her ordinary life again. This she continued to do without feeling ill and with practically no variations in the symptoms till just before Christmas, 1907—i.e., for two years. The cyanosis persisted but was less marked in hot weather, the spleen remained about the same size, and the urine always contained about one-fourth albumin. There was no subsequent attack of hæmaturia, epistaxis, or any other kind of hæmorrhage. Menstruation only occurred at long intervals and was always scanty. During this period I kept her under constant observation and treatment was chiefly directed towards attempts to establish regularity of the menstrual function and to effect dilution and to diminish the coagulability of the blood. For several months large quantities of saline fluid were taken regularly: citric acid, citrates, and iodide of potassium were all tried persistently, but nothing had any effect on the cyanosis, the spleen, or the condition of the blood. At first, and for some time, diet consisted of milk and farinaceous food, but gradually fish, poultry, and a little meat were permitted.

Just before Christmas, 1907, some indistinctness in speech was noticed, and this was attributed by the patient to a crack in a dental plate. I accepted the explanation and allowed her to go to Yorkshire for the Christmas holidays. On her return it was evident that she had chorea and that this, and not the dental plate, was the cause of the imperfect articulation. The patient was, of course, ordered to bed. The left side of the body was first attacked and the leg most severely, but the whole of the body quickly became affected. Almost immediately she complained of aching pain in the left side of the neck, and this I attributed to the choreic movements; in a few hours, however, this proved to be due to thrombosis of the jugular vein, and swelling of the left arm appeared.

As the condition now appeared to me to be serious, I asked Dr. H. G. Turney to see the patient with me. This consultation took place on Jan. 9th, 1908, and I cannot do better than give an extract of some notes made by Dr. Turney, a copy of which he kindly sent me. "Patient is quite clear mentally; talks with animation and without difficulty, except that due to the choreic movements. These affect trunk and limbs alike. There are no signs of paralysis; reflexes are everywhere present and normal in character. There is a strikingly cyanotic tint over the whole body. This tint is not limited to the cheeks or mucous membranes, but is remarkably uniform. The left side of the chest and the whole of the left upper limb are much swollen. The skin here is absolutely purple, the colour being most intense about the infraclavicular region and the left shoulder. Large veins are visible by their deeper colour, and can be rolled under the fingers as solid cords. This consolidation can be traced up the neck along the course of the jugular vein as far as the angle of the jaw. There is no œdema of face, eyelids, mastoid region, or scalp. The venous plugging is not perceptible in the axilla or down the arm. On the right side of the chest the veins are moderately distended, contain fluid blood and pulsate, the pulsation having presystolic rhythm. The hypogastric veins are more visible than usual. The lower limbs are not œdematous. There are large purpuric patches over both knees and smaller ones over the ankles. The venous pressure, calculated by Dr. George Oliver's method, showed a pressure of at least 40 mm. of mercury, as the veins on the dorsum of the right hand did not collapse, even when the limb was held vertically. [There was no thrombosis in the right arm at this time, and it did not appear till several weeks later.] The radial pulse is very firm and tense and does not subside during the diastolic period. With Martin's modification of the Riva-Rocci sphygmomanometer the high pressure of 170 mm. was registered. The pulse, which was 120-140 during examination, was regular. The heart sounds are clear. The spleen reaches 4 inches below the ribs; it is firm on palpation and not tender. The kidneys are large and moveable, the right more than the left. The urine contains a considerable amount of albumin, but no blood. The temperature is normal. The pupils are equal and active; there is no squint or nystagmus. The fundi are normal, except that the veins are large and tortuous." Bromide and citrate of potash were given as medicine and the left arm was kept elevated and bandaged.

The chorea became very severe, and after a few days, as no relief was obtained, phenazonum was tried. Under this drug the chorea rapidly subsided. The œdema of the left arm diminished slowly, the intense dark colour gradually disappeared, and the limb reassumed its former colour. The jugular vein and the superficial veins on the shoulder remained blocked. On Feb. 16th the patient was allowed to get up for a short time and continued to improve for a few days. On the 26th choreic movements in the left foot reappeared and the patient was again kept in bed. On the 28th she complained of pain in the region of the spleen, which was distinctly tender on pressure; there was a slight rise of temperature, but after two or three days the pain, tenderness, and fever disappeared. On March 2nd swelling of the left thigh was noticed, and pain was complained of in the hypogastric and left iliac regions. Examination per vaginam revealed nothing abnormal. On the following day the whole leg and foot were œdematous and almost black in colour, as the arm had been. There was also a good deal of pain in the thigh and calf. The leg was bandaged and kept elevated. On the 4th the right leg began to swell and on the following day became very dark and swollen like the left. This discolouration soon extended on to the abdomen up to a sharply defined line at the level of the umbilicus; whilst the face, arms, and upper half of the trunk were not nearly so cyanosed as usual. The abdominal superficial veins became also very much distended. Both legs now were kept elevated and bandaged. The vulva became œdematous and such obstruction to micturition was caused that it was feared a catheter might have to be used. This was not, however, necessary, although the vulva still remained much swollen, especially on the left side. Petechial extravasations along the course of the small veins appeared on the lower half of the abdomen, and the abdominal wall and back became rapidly œdematous. On the 10th the spleen, which had been noticed to be getting smaller since the legs had been thrombosed, only extended below the ribs for about an inch. The amount of urine passed during the last days had been about 60 ounces per diem and contained much less albumin than I had ever previously noted. Small ulcers now appeared on the inner side of the lips and cheeks and on the tongue, and the chorea became worse again. On the 21st the ulcerative stomatitis, which had caused great discomfort, had disappeared under the exhibition of chlorate of potash, and the choreic movements had also again ceased. The legs had been very painful, necessitating lead and opium fomentations, and were still very œdematous, though not quite so dark in colour. Aching pain was now complained of in the right axi[illegible] and lower part of [illegible] dark. The right [illegible] puffy, and the spleen was noticed to be getting larger again. A slight cough was now first noticed; but no physical signs could be detected in the lungs. On March 25th the abdominal wall and back were very œdematous, but no free fluid could be detected in the abdominal cavity. The amount of urine passed per diem was now about 40 ounces only and contained no albumin. The patient seemed a little drowsy at times. The cough had become much more troublesome and respiration was quicker. The lungs were resonant all over; air entered well right down to the bases and there were no moist sounds. On the 27th the temperature was 100° F. and the pulse was 140; the usual rate for some time had been about 116; the tongue, however, was clean, and the appetite remained good.

On March 28th the patient was decidedly worse; the pulse was slightly intermittent, and the respirations were 36 per minute and shallow. Œdema of practically the whole of the body now existed but was greatest over the lower half of the abdomen and back. The legs, however, were still kept elevated. During the evening, breathing became, somewhat suddenly, very rapid and laboured, and though it improved after a short time, in the early morning of the 29th it became again much worse. When I saw the patient at 4 A.M. the dyspnœa and restlessness were most distressing. I could still detect nothing in the lungs; air entered well all over and resonance was unimpaired. I yielded to her entreaties to be placed in an armchair, and after this had been carefully done the dyspnœa was considerably relieved. After some two hours in this position she went back to bed and had some sleep. On the following day she expressed herself as feeling much better. The respirations were still very quick, 42 per minute, but the patient was certainly much more comfortable. She remained in bed all day, well propped up with pillows, and took nourishment well, although some more ulcers were beginning to appear in the mouth. She was passing very little urine. She had a much better night, with several sleeps of over an hour's duration. The cough was, however, troublesome and the respirations were 50 per [illegible] she seemed decidedly [illegible] in his mind, for town. [illegible] with the most intense dyspnœa, and when I saw her half an hour later she was unconscious and in a moribund condition. The breathing was gasping in character, the radial pulse was almost imperceptible, and the cyanosis of the face was intense. Strychnine and digitalin injections were given hypodermically and oxygen was freely used, but although a slight improvement in colour took place consciousness never returned and death occurred shortly after 2 P.M. in the afternoon. No post-mortem examination was performed. Unfortunately, a blood count had not been made for some time, as I had put it off from day to day owing to the serious condition of the patient.

The occurrence of thrombosis in a case of this disease seems to be a complication that one would almost expect, and yet, as I said, I have seen no mention of such general thrombosis in any of the cases published hitherto. Dr. Turney has, however, seen one case in which thrombosis occurred in the veins of the leg and was followed by a transient hemiplegia, the mode of onset of which, quite apart from thrombosis in the leg, made the diagnosis of cerebral thrombosis the most probable. The main veins in all four limbs and both sides of the neck became blocked and remained so, and though in the left arm a collateral circulation was established, with diminution of the cyanosis and œdema, in the other limbs no such amelioration of symptoms occurred. In the lower part of the body thrombosis commenced in branches of the external and internal iliac veins and ultimately the thrombosis, I think there is little doubt, spread to the inferior vena cava and the right side of the heart. The cough and dyspnœa at their onset might have been due to minute emboli in the smaller pulmonary arteries but more probably were due to thrombosis in the veins, and these symptoms were unaccompanied by any physical signs in the lungs that one could detect by the stethoscope or percussion. The fatal attack, too, was most probably due to thrombosis extending to the right side of the heart, blocking its valves and thus causing death—though there is the possibility of a large pulmonary embolism arising from a detached clot being the cause.

The association of the chorea with the thrombosis is extremely interesting. In cases of chorea associated with endocarditis, embolism of the smaller cerebral arteries, arising from vegetations carried from the mitral valve, has been one theory advanced as the cause of the disease. In this case there was absolutely no evidence of any endocarditis, affection of the mitral valve, or history of rheumatism, and therefore no condition likely to have given rise to cerebral embolism, but there is a strong probability that thrombosis first occurred in the smaller cerebral veins before appearing elsewhere and that the chorea was directly caused by this pathological condition.

The case seems to me to afford additional evidence in support of the theory that chorea is associated with embolism or thrombosis of some of the blood-vessels of the brain. On the other hand, the particularly clear mental condition right up to the end seems to negative any extensive cerebral thrombosis.

Sydenham, S.E.

ADENOIDS, NOCTURNAL INCONTINENCE, AND THE THYROID GLAND.

BY LEONARD WILLIAMS, M.D. GLASG., M.R.C.P. LOND.,
PHYSICIAN TO THE FRENCH HOSPITAL, SHAFTESBURY-AVENUE, LONDON, W.C., ASSISTANT PHYSICIAN TO THE METROPOLITAN HOSPITAL, KINGSLAND-ROAD, N.E.

IN the autumn of 1908 I was instrumental in obtaining a presentation to Christ's Hospital for a boy, aged nine years, and he was admitted on Sept. 16th. When he had been there for seven weeks his mother was informed that he had twice suffered from nocturnal incontinence, which was an old but infrequently recurring trouble with him, and that if this happened again he would have to be removed until he was cured. It did happen again. The boy was accordingly brought to town and I asked Dr. StClair Thomson to examine him with a view of ascertaining whether he was the subject of adenoids. Adenoids, according to the text-books, are one of the two commonest causes of nocturnal incontinence. The other, phimosis, could be excluded, the boy having been circumcised as a baby. Dr. StClair Thomson found that adenoid vegetations were present, but while agreeing to operate he warned me that he had frequently known nocturnal enuresis to persist after very thorough removal of adenoids and tonsils, even in cases where no other cause could be discovered.

The operation was performed on Dec. 12th and the patient made an excellent recovery. On the 15th he was allowed out of bed and seemed quite well. That night he wetted his bed and continued to do so on each of the next 15 nights—i.e., until Dec. 29th. In every other way he was perfectly well.

The removal of the adenoids and tonsils, so far from ameliorating his condition or holding out any hope of ultimate cure, had thus quite evidently aggravated it; for whereas formerly the incontinence occurred at intervals of weeks it had now become regular and persistent. The extent to which the bed was wetted was such as to suggest that the [illegible], and this in spite of [illegible] the child out of bed [illegible]

The position was a serious one. The patient was the son of a widow who was entirely dependent upon her own exertions, and the condition of his return to Christ's Hospital was that he should remain free from nocturnal enuresis for three months. How was that freedom to be secured? Large and increasing doses of belladonna, the classical remedy of the text-books, naturally suggested themselves; but even if they *succeeded*, their continuance, in the case of a boy at a large public school, presented serious and even insuperable difficulties. Was there no other course? A consideration of the events above related suggested to my mind the possibility that the removal of the adenoids had deprived the patient of some internal secretion which up to that time had partially protected him against these accidents; that, in fact, the adenoids, instead of representing a superfluity of naughtiness on the part of the organism, had, in reality, been developed for some useful purpose. In pursuance of this idea I decided to try the effect of thyroid extract. The thyroid gland has very intimate relations with the lymph glands, and adenoids consist of lymphoid tissue. Superficially there was not much encouragement to be obtained for this experiment from the boy's general condition. He was spare rather than stout, and so far from being lethargic he was very bright and intelligent. He was, however, undersized, being shorter by two inches than the average for his age. His pulse-rate was 74, his blood-pressure 100 millimetres of mercury. He began taking thyroid extract in Burroughs and Wellcome's tabloids of half a grain, one night and morning, on the night of Dec. 30th. The effect was most dramatic. The enuresis immediately ceased and, under the influence of the thyroid treatment, it has never since recurred. On Jan. 5th, 1909, that is, six days after the treatment was commenced, he had gained over five pounds in weight (from 4 stones 4 pounds 4 ounces to 4 stones 9 pounds 7 ounces), and on the 13th he reached 4 stones 11 pounds—the average for his age, at which he has remained. As the dose of half a grain (which I had tendered in the first instance not without misgiving) was so well borne on Feb. 14th I increased it to two and a half grains three times a day, thereby taking a step which, as will appear later, was so dangerous that it might very easily have turned success into disaster.

In view of so simple an issue from what threatened to be a calamitous *impasse*, I searched the literature to see whether any similar case had been reported. English authorities, both on the subject of enuresis and thyroid medication, I had already exhausted without finding a hint as to a possible connexion between the two. I now turned with some confidence to the recently published work of Léopold-Lévi and Henri de Rothschild,[1] some scattered papers by whom I had read in periodicals. Here I found the subject of enuresis mentioned on several occasions in connexion with patients who were the subject of thyroid insufficiency, but the mention in each case was merely incidental, and nothing was said as to the effect of the treatment on the enuresis. In the course of the book, however, I found several references to the work of a Belgian writer, Dr. Hertoghe of Antwerp, who had evidently made the thyroid gland an object of careful observation. I therefore consulted his writings, and amongst them there is a paper read before the Royal Academy of Medicine of Belgium entitled "Nouvelles Recherches sur les Insuffisances Thyroidiennes; l'Incontinence d'Urine Nocturne chez les Enfants et les Adolescents,"[2] in which the author insists strongly on the curative influence of thyroid extract in nocturnal enuresis and quotes some convincing cases. A perusal of this paper, overlaid though the subject is with much extraneous matter, encouraged me to try the effect of the treatment on children in the out-patient room of the Metropolitan Hospital, and I accordingly asked Mr. Sydney Vosper, now the senior house physician, to collect as many cases of the kind as he could. But for this gentleman's willing and even enthusiastic coöperation, of which I desire to express my warmest appreciation, it would have been impossible to have brought the investigation of the subject to its present point.

We have seen in all 25 cases. Of these only one has failed to respond to the thyroid treatment. The failure in this case (Case 12, quoted hereafter) was absolute and unequivocal. Of the remainder some were brilliantly successful, all were improved, and in no case has the thyroid extract produced any of those untoward effects of which we are taught to beware.

CASE 1.—The patient, a girl, aged 11 years, was first seen on Feb. 2nd, 1909. She had wetted her bed every night since birth. For the last few years she had in consequence slept on straw. She was dull and apathetic but not stupid. She was thirsty but her appetite was poor. The patient was not undersized and her weight was 5 stones 1 pound. The tonsils were somewhat enlarged, but there were no adenoids or nasal obstruction. The temperature was 99° F. in the mouth. One and a half grains of thyroid extract three times a day were ordered. Feb. 9th: The patient had missed wetting her bed for the last three nights—the first in her life. The same dose of thyroid extract was ordered. 16th: On three successive nights the bed had not been wetted. The dose of thyroid extract was increased to two and a half grains three times a day. 23rd: No enuresis had occurred during the week. Thyroid extract was ordered as before. March 2nd: No enuresis. 9th: No enuresis. 12th: No enuresis.

CASE 2.—The patient, a girl, aged nine years, first came to the hospital in May, 1908, complaining of cough, dyspepsia, and anæmia. Examination revealed nothing definite and a provisional diagnosis of pretuberculosis was made. Nothing was said about noctural enuresis and it was not inquired for. The patient improved under cod-liver oil and iron. On Feb. 5th, 1909, ten months later, she returned, and the fact of the enuresis was then elicited. The child, it appeared, had suffered without intermission from diurnal polyuria and precipitancy, as well as nocturnal incontinence, since birth. She was thin and anæmic but had no nasal obstruction. She was intelligent but tearful. The cod-liver oil and syrup of iodide of iron were repeated, and she was given in addition one and a half grains of thyroid extract four times daily. 12th: The patient had missed wetting her bed on six days out of the seven, the first in her life. She remained away from the hospital for 14 days, during the last seven of which she was without thyroid extract. During the first seven days she wetted the bed once, and during the second twice. The treatment was continued. March 5th: No enuresis. 12th: No enuresis. 16th: No enuresis.

CASE 3.—The patient, a boy, aged eight years, was first seen on Feb. 5th, 1909. He had wetted himself by day as well as night since birth, was very backward at school, and was undersized, being only 3 feet 4 inches instead of 3 feet 11 inches in height, while his weight was only 2 stones 11 pounds instead of 3 stones 13 pounds. He was a voracious and rather indiscriminate feeder. Two months previously he had been put on the table for *adenoids*, but it was found that he had a febrile temperature, so the operation was postponed. The temperature now was 97·2° F. He was given two and a half grains of thyroid extract *four times* daily. On the 12th the mother reported that during the week the patient had not had a single diurnal accident, and that he had only wetted his bed twice. He was brighter. 19th: The patient had wetted his bed once only during the week. March 5th: The bed had been wetted twice during the week. 9th: There had been no enuresis. 16th: No enuresis. 23rd: No enuresis. The temperature was now 98·4°. The patient no longer breathed through his mouth.

CASE 4.—The patient, a boy, aged three years, was first seen on Feb. 16th, 1909. He had been wetting his bed two or three times a week for three months. He had been subject also to noctural attacks of diarrhœa, not infrequently accompanied by vomiting. There were adenoids, a large abdomen, and beads on the ribs. The patient's weight was 2 stones 1 pound 8 ounces and his temperature was 96·4° F. He was given one and a half grains of thyroid extract three times a day. 23rd: The bed has been wetted once only during the week. The dose of thyroid extract was increased to two and a half grains. March 9th: There had been no enuresis for a fortnight and no attack of diarrhœa. 16th: There had been no enuresis; 5 pounds in weight had been gained, the abdomen was less prominent, and the patient was much brighter. He snored less at night and kept his mouth closed.

There are three other cases (Cases 5, 6, and 7), those of a girl aged eight years, a boy aged three years, and a girl aged ten years, which are in every way as satisfactory as those above quoted. There are four others (Cases 8, 9, 10, and 11) in which the patients, after showing decided *improvement*, disappeared, after the manner of *out-patients*, and have not so far been traced.

CASE 12.—This case, the subject of which was a girl aged seven years, is the only one which has up to the *present* shown no signs of improvement. The patient was brought to the hospital on Feb. 16th, 1909, with the *story* that she had wetted her bed, generally more than once a night, ever since her birth. The parents had had one other child who had died from a cause unelicited. The patient had always been delicate. She was not, however, undersized, and her weight of 3 stones 7 pounds was up to the average. The temperature was 98° F. She had enlarged tonsils but free nasal respiration. She was given two and a half grains of thyroid extract night and morning. On the 23rd the mother was of opinion that, although the enuresis had occurred every night, there was an improvement, inasmuch as it did not occur so often nor so soon after retiring. The thyroid extract was ordered to be taken four times daily instead of twice. On March 2nd there was no improvement. The mother thought the child worse in every way. On the 9th there was no improvement; she was therefore given iodine and arsenic in addition to the thyroid extract. On the 12th there was still no improvement. She had lost weight; her temperature was 99°.

[1] Etudes sur la Physio-Pathologie du Corps Thyroide (Octavo Doin, 1908).

[2] Bulletin de l'Académie Royale de Médecine de Belgique, IV. Série, Tome XXI., No. 4.

The remaining 13 cases, some of which have been but a short time under treatment, all show very definite evidences of amelioration, though none can as yet be described as complete cures. The response in each case has, however, been so decided as to encourage the confident hope that a continuance of the thyroid treatment, reinforced if necessary by iodine, arsenic and calcium, all of which have direct relations with the functions of the thyroid gland, will ultimately be attended with perfectly satisfactory results. I append three typical cases, numbering them 13, 14, and 15.

CASE 13.—The patient, a boy, aged 13 years, had always suffered from nocturnal enuresis, for which he had in vain sought relief at various hospitals. He also complained of abdominal pain at night. He had a high arched palate and large tonsils. Examination confirmed the presence of adenoids, which his appearance suggested. One brother had a hare-lip. The patient was undersized, being 4 feet 6 inches instead of 4 feet 9 inches in height, and he weighed 4 stones 11 pounds instead of 5 stones 3 pounds. At school he was only in the third standard; he ought to have been in the sixth. He was given two and a half grains of thyroid extract night and morning. On Feb. 23rd he reported having been free from enuresis on four nights, and the nocturnal pains were less. The dose of thyroid extract was increased to five grains night and morning. On March 2nd it was ascertained that, though feeling much better, he had been free from enuresis on one night only. 9th: The patient had had four nights of freedom. 16th: Four nights of freedom. 23rd: No enuresis. The patient had gained weight, he snored much less at night, and his nasal respiration was improved. The abdominal pains no longer troubled him. He was given a tonic in addition to the thyroid extract.

CASE 14.—The patient, a girl, aged six years, was first seen on March 2nd, 1909. She had begun to wet her bed two months previously after an attack of mumps, but had not done so before. Since then she had suffered from constant nocturnal enuresis and frequent diurnal accidents. Digital examination revealed adenoids. The weight and temperature were normal. She was given two and a half grains of thyroid extract night and morning. On the 9th it was ascertained that during the past week she had wetted the bed on two occasions only and that there had been no diurnal accident. The appetite was much improved and the patient was brighter. The thyroid extract was ordered to be taken three times a day instead of twice. 16th: The bed had been wetted every night; a tonic was therefore given in addition to the thyroid extract. 23rd: There had been one night of freedom. The dose of thyroid extract was reduced.

CASE 15.—The patient, a boy, aged eight years, was admitted to the French Hospital on Feb. 22nd suffering from bronchitis. His mother stated that he had had noctural enuresis and diurnal accidents without any intermission since birth, and had been ineffectually treated in the Paris hospitals for this condition. He had no phimosis, no adenoids, and only moderately enlarged tonsils. He had always been apathetic and tearful. He was given one and a half grains of thyroid extract three times daily. In spite of the fact that he was taken up once and sometimes twice a night the nocturnal enuresis continued unabated for ten days, but the diurnal accidents ceased. On March 4th, in addition to the thyroid extract he was given iodine and arsenic, and on the 6th he began to improve. On the 8th the dose of thyroid extract was increased to two grains, and the nurse was told not to get him up at night. On the 11th, 12th, and 13th there was no enuresis, and during the following week it occurred on three occasions only. The child became much better. The temperature, however, remained low, from 96·2° to 97·2° F.

The deductions to be drawn from this inquiry are several, if not many, but as I am anxious to avoid overloading the present communication I will restrict myself to what seem to be the most important.

The first is that adenoid vegetations can no longer be regarded as a cause of nocturnal enuresis. Without at present going so far as to say that, as suggested by the case which forms the opening part of this paper, the adenoids afford some measure of protection from nocturnal accidents of this nature, I feel justified in asserting that when the two conditions are associated, which they often are, but as often are not, they are both due to a common cause—namely, insufficiency of the internal secretion of the thyroid gland. This insufficiency accounts for the vast majority of cases of nocturnal enuresis in children, as shown by the fact that the exhibition of thyroid extract will in a comparatively short space of time effect not only a cure of the enuresis but a great amelioration of many coexisting evidences of ill-health. It will be observed that in none of the above cases have belladonna and hyoscyamus, which constitute the somewhat slippery and brutalising sheet-anchors of the text-books, played any part in the treatment. Where it was thought desirable to employ anything in addition to the thyroid extract, these additions have consisted of tonics such as iron, arsenic, and iodine.

The very remarkable improvement in the general health of the patients under treatment for enuresis by thyroid extract induced me to try the effect of the drug on two or three children who suffered from debility due to other causes. The case of one of these affords a lesson which it is well to lay to heart, a lesson which, had it presented itself sooner, would, I believe, have saved me from some disappointments and possibly from my one complete failure. It was that of a boy, aged nine years, who had been under treatment on and off for two years for general debility consequent on an attack of nephritis from which, so far as physical signs were concerned, he recovered perfectly. He had a rickety thorax but no adenoids. He did not suffer from nocturnal incontinence and had a normal temperature and a normal palate, but the miracles wrought by thyroid extract in the other cases moved me to give it a trial in his case. He was therefore given two and a half grains three times daily in addition to the cod-liver oil which he was already taking. The result [illegible] then frame of mind, it was [illegible] week of thyroid extract tre[illegible] in his life, suffered from nocturnal enuresis. The obvious inference from this was that the thyroid secretion is a regulator of the mechanism by which urinary incontinence is controlled, an [illegible] of the secretion being almost, if not quite, as deleterious [illegible] is brought home to me I [illegible] I now recognise that in the treatment of enuresis by thyroid extract the question of dosage is not only of paramount importance but also of the utmost delicacy. It is essential to success that the initial dose should be very small; that this dose should be increased very cautiously, if [illegible] dose which experience proves [illegible] should be steadily persevere[illegible]y, by such [illegible]tioned. The cause of failure [illegible] been not so much a want of [illegible]ation on the part of the [illegible]y part in regulating the dose, and if I am successful in tracing this patient I shall undertake her treatment on this hypothesis with very considerable confidence.

Harley street, W.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.—The summer term at the National Hospital in Queen-square will commence on May 4th with a lecture by Dr. J. S. Risien Russell on the Significance of Paralysis in Cranial Nerves. Clinical lectures and demon[illegible] will be held at 3.30 P.M. on the following [illegible] (with the exception of June 1st) until J[illegible]

STREPTOCOCCAL PERICARDITIS AND COLITIS FOLLOWING TONSILLITIS.

By J. SIDNEY PEARSON, M.A., M.D. CANTAB.,
LATE RESIDENT MEDICAL OFFICER, EAST LONDON HOSPITAL FOR CHILDREN, SHADWELL.

THE two cases recorded below are, I think, of some interest on account of their similar and unusual symptoms and as warning of the possible dangers from an apparently slight attack of follicular tonsillitis. I do not think that the colitis was a mere incidental complication. In neither case did it give rise to any symptom until the hæmorrhage occurred.

CASE 1.—The patient, a well developed, healthy-looking girl, aged 20 years, was treated on April 26th, 1907, at St. Mary's Hospital, Plaistow, for follicular tonsillitis. On the 28th she had pain in her limbs but no trouble in any of her joints. The tonsillar condition was well by the 30th, but the pains had not yielded to salicylates. On May 3rd her temperature was found to be 105·6° F. and she was admitted into the hospital under the care of Mr. S. J. Wareham. The only points in the history were that her mother, who was in the country, "suffered with her heart." The patient had always had trouble with her bowels and had been treated two years previously for chlorosis.

On admission she did not appear to be very ill. The temperature was 105° F., but she was quite conscious and took a great interest in her own condition. Examination revealed pain on pinching the muscles, especially the thighs. There was no pain in the joints. There were a few small pustules on the buttocks. The heart sounds were well heard and there was no increase of cardiac dulness. She was put on a mixture containing sod. salicyl. gr. xv. every two hours, and shortly the temperature fell to 102°. On the evening of May 5th it rose again to 105°, but the patient seemed no worse. Typhoid fever was suspected, but there was no evidence, and Widal's reaction was negative throughout her illness. On May 6th the temperature was 106·8°, but there was no sign of delirium. Cardiac dulness had increased up to the second left space, and later in the day pericardial friction was detected for the first time. On the 8th the patient became drowsy and later delirious. On the 9th there was incontinence of loose fæces. On this day the urine, which had contained albumin throughout, was found to have a trace of blood in it and the next day was quite dark red. Pustules appeared on the outer aspects of the soles of the feet. There was no œdema or desquamation. On the 10th I heard from Dr. J. W. H. Eyre of Guy's Hospital that he had obtained a pure culture of streptococcus longus from the blood. Antitoxin was given on the following day, but her condition remained the same. On the evening of the 12th the patient suddenly passed about two pints of dark red blood per rectum and died shortly afterwards. The stools, which had been watery, had not shown a sign of blood previously. A post-mortem examination revealed intense inflammation of the pericardium, which contained about two ounces of thin pus. The layers were rough, shaggy, and thickened. There was no endocarditis, the valves being healthy and competent. The whole length of the large intestine was studded with shallow, irregular ulcers varying in size from a threepenny-bit to half a crown. One large and deeper one was seen in the descending colon.

CASE 2.—The patient, a girl, aged seven years, was admitted on July 23rd complaining of pain in the knees, which, however, were neither red nor swollen. Five days previously she had had an acute tonsillitis, of which there was still slight evidence. No history of rash was obtained. The cardiac sounds were normal. The apex beat was in the fifth space nipple line. The temperature was 102·6° F., the pulse was 144, and the respirations were 42. She was put on sod. salicyl. gr. xv. every four hours. The temperature fell in a few hours, but pains persisted. The temperature was as high as ever on the next day, and on the following rose to 105·4°. Pericardial friction was now heard, and there was increased cardiac dulness. On the evening of the 29th I discovered an unusual phenomenon. The temperature in the right axilla was 102°, compared to 106·4° in the left, whilst the rectal temperature was 104°. I confirmed this by two thermometers, placing them in different positions, but always with the same result. The child became very apathetic, and later delirious. The streptococcus longus was grown from the blood and 10 cubic centimetres of anti-streptococcic serum were injected daily. On August 7th and 9th the child passed about two ounces of bright red blood per rectum and after this the stools were often blood-stained. Pustules appeared on the buttocks on the 12th. On the 14th the child began to improve. The heart sounds became more audible and the dulness less. She left the hospital on Sept. 14th for a convalescent home and returned a month later quite well. She was on various drugs, including five grains of sodium sulphocarbolate, which seemed to improve her, but I should not like to lay any stress on this.

These two cases were so much alike that I was prepared for the late developments in the second case. The hemipyrexia was discovered by a nurse, and since this case I have frequently observed that in acute pericardial effusions the temperature in the left axilla is often a degree higher than in the right; in fact, I look upon this sign when present as very suggestive of pericarditis and one which may be useful when the auscultatory signs are doubtful.

I am indebted to Dr. E. B. Randall and Mr. Wareham for permission to publish their cases.

A SIMPLE METHOD FOR THE STERILE COLLECTION OF BLOOD.

By HUGH W. BAYLY, M.R.C.S. ENG., L.R.C.P. LOND.,
ASSISTANT, BACTERIOLOGICAL DEPARTMENT, ST. GEORGE'S HOSPITAL.

WHEN collecting numerous samples of bloods by venipuncture the use of a syringe necessitates a considerable waste of time as the syringe cannot, after use, be plunged into boiling water without great danger of cracking, neither can it be safely removed from boiling water. If the temperature is gradually raised to boiling point and then lowered about ten minutes will be required for each case. If an all-metal syringe is used it is impossible to see whether the blood is flowing into the barrel properly. Also, if a metal plunger is used and pure uncitrated blood is required (as is the case when the blood is required for the serum diagnosis of syphilis), the thin film of blood between the plunger and the barrel is liable to clot, when the plunger becomes immoveably fixed in the barrel. This is obviated by lubricating the plunger with oil or vaseline, but as this must be done after sterilisation there is an added opportunity for contamination. If a rubber plunger is used it is not always smooth and satisfactory in working in a dry barrel.

I have, with Dr. Charles Slater's kind help, devised the following simple little apparatus which I find quite satisfactory, and which permits of the collection of 18 samples in an hour of whatever quantity may be required. Instead of a syringe I use a hollow metal needle holder two and three-quarter inches long, having a finger-grip half an inch from the nozzle end. The bulbous distal end is connected by about four inches of rubber tubing with a sterile test-tube, into which the blood flows directly (see Fig. 1). I use needles one inch long and with the calibre of a large exploring needle. J. H. Montague, of 69, New Bond-street London, W., has made me a small case containing 18 needles

FIG. 1.

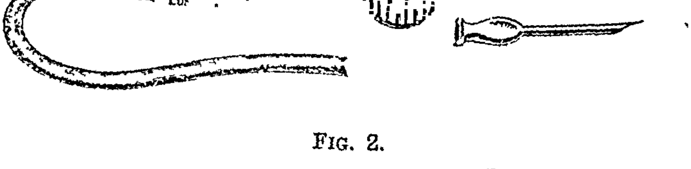

FIG. 2.

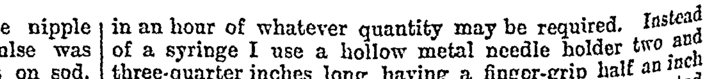

and two holders, and while I am using one holder, the other, with tubing attached, is being sterilised.

I use a fresh needle for each case, and the needle will slip into the vein with ease if lubricated with a little sterile vaseline, and for this purpose I use a five cubic centimetre serum flask, filled to the shoulder with vaseline, which is autoclaved at 120, and after the vaseline has solidified a few drops of izal are introduced into the neck of the flask, which is then covered with a sterilised rubber teat. The needle, immediately after removal from the steriliser, is dipped into the vaseline before use. After use the holder and tubing should be washed through with a small glass urethral syringe to remove the blood before placing in steriliser.

If the patient objects to venipuncture, which is seldom the case, I use the glass tube depicted in Fig. 2 with which I can easily collect one cubic centimetre from the finger. The tube is made from No. 4 glass-tubing with one end drawn out into a capillary tube and the other end sealed and a bulb blown near the drawn-out end with a small hole blown in its side (see Fig. 2). The tube is held with the hole in the bulb uppermost and the blood will flow into the bulb by capillary attraction and then collect in the sealed end, the displaced air escaping through the hole in the bulb. After filling, the drawn-out end is sealed in the flame and the hole in the bulb is sealed with wax.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A NOTE ON SOME NON-TUBERCULOUS THROAT COMPLICATIONS OF PHTHISIS.

By Harold S. Barwell, M.B. Lond., F.R.C.S. Eng.,
SURGEON FOR DISEASES OF THE THROAT, ST. GEORGE'S HOSPITAL,
SURGEON TO THE THROAT AND EAR DEPARTMENT, HAMPSTEAD
GENERAL HOSPITAL, LATE LARYNGOLOGIST, MOUNT
VERNON HOSPITAL FOR CONSUMPTION, ETC.

TUBERCULOUS laryngitis is by far the most important of those complications of phthisis which affect the upper respiratory tract, so much so, indeed, that it is apt to overshadow all the others and to receive the exclusive attention of the laryngologist as well as of the physician. Nevertheless, other complications are very frequently encountered

claim some consideration.
the larynx has often been
ems to mean an abnormal
congestion, or swelling of
it but without as yet any

true tuberculous deposit, and it is implied that this is a precursor of tuberculous infiltration. The use of this expression appears highly unscientific, for there are no grounds for the view that there is any distinctive state of the larynx which is always, or frequently, followed by tuberculosis. There is also a very general opinion that pallor of the larynx is a characteristic feature of tuberculous laryngitis, but this opinion requires qualification. Many consumptives are anæmic, and in such cases the larynx, as well as the fauces and other mucous membranes, are, of course, pale; in other cases the colour is quite normal, and very frequently the tuberculous larynx is in a state of hyperæmia as the result of coughing and irritation; in fact, it may be stated that tuberculous larynges are reddened quite as frequently as unduly pale. It is true that the swollen infiltrated arytenoids are often pallid, and that the margins of tuberculous ulcers are characteristically anæmic, and this may have given rise to some misconception; but very often tuberculous infiltration is decidedly red and congested, especially on the cords, ventricular bands, and epiglottis.

Simple chronic pharyngitis and laryngitis are extremely common among consumptive patients and not infrequently give rise to mistakes in diagnosis, for there is naturally a tendency to diagnose tuberculous laryngitis in a phthisical patient who complains of hoarseness and discomfort in the throat. The frequency of simple inflammation of the larynx may be explained by the strain of constant coughing and by the contact with irritating sputum which contains numerous micro
their products in addition to the tubercl
the absence of other distinctive signs a unifor
both vocal cords should not be diagnosed as t
but if one cord be affected markedly in excess of
tuberculosis may be strongly suspected. The subj
active phthisis often complain of much dryness and
comfort in the throat, especially at night, even when there
no obvious nasal obstruction. This appears to be the resu
of the nocturnal pyrexia and the consequent rapid respiration which makes nasal breathing insufficient. A drink of hot milk or a demulcent lozenge diminishes the sense of discomfort. Patients in quite an early stage of phthisis sometimes complain of painful sensations about the throat which on examination appears perfectly normal. The cause of this is obscure; it may, perhaps, be that the pain is referred from the pulmonary disease to the most sensitive part of the respiratory system. Be that as it may, the symptom is not very uncommon, and I would suggest that the patient who complains of pain about the larynx for which no cause can be found should be submitted to a careful examination of the chest.

Pachydermia laryngis is also disproportionately common among the subjects of pulmonary phthisis; indeed, Gougenheim[1] considered the majority of cases of pachydermia to be tuberculous. I personally consider the affection as an extreme form of chronic laryngitis and due to the same causes; it is therefore natural that it should be frequent in the larynges of consumptives exposed to the mechanical irritation of coughing and the chemical irritation of the sputum without, of necessity, any entrance of the bacillus tuberculosis into the tissues. The firm white, almost cornified, appearance of a typical case is very different from the soft semi-translucent granulations of tuberculous laryngitis. On several occasions I have removed the pachydermatous thickening from the posterior commissure of consumptive patients and have failed to find any sign of tuberculosis on microscopical examination.

It is well known that in c
voice is readily lost and is
would be with a similar
cause, such as syphilis. But apart from any laryngeal affection, functional aphonia is very common among consumptive patients. The feeble respiration, the general weakness, and the tendency to catarrh and discomfort of the throat all conduce to this affection, which is found in male as well as female consumptives, though more frequently in the latter. It is so frequent that an examination of the chest is advisable in every case of intractable functional aphonia. True paralysis of a vocal cord is also a recognised complication of pulmonary phthisis. It is due to pressure on the recurrent laryngeal nerve, and is therefore of the abductor type. Paralysis of the left cord is the result of pressure on the left recurrent laryngeal nerve by enlarged bronchial or tracheal glands, but the right nerve passes very close to the apex of the right pleura and is thus sometimes directly involved in an infiltration of the lung on this side. This is, perhaps, the commonest cause of paralysis of the right vocal cord, therefore the possibility of pulmonary phthisis should always occur to the mind of the observer who discovers this lesion on laryngoscopic examination.

Thus, other complications of pulmonary phthisis occur in the throat besides tuberculous laryngitis, and deserve recognition; and in a few cases where the first complaint is of the throat a correct estimate of their significance may direct the attention to the pulmonary disease.

Wimpole-street, W.

NOTE ON A CASE OF JACKSONIAN EPILEPSY TREATED BY TREPHINING.

By W. Bernard Secretan, M.B. Lond., F.R.C.S. Eng.

THE following are notes of a somewhat unusual case of Jacksonian epilepsy, in which cessation of the fits was brought about by operation.

The patient was an anæmic woman, aged 24 years. Her occupation was that of a clerk. About 16 years ago she fell down a flight of steps on to her head. She was not stunned at the time and was apparently able to get up by herself and go home. Eight days after, however, she developed a very severe headache, which was followed the same night by three convulsions affecting the left arm and leg. Each convulsion lasted only a short time. The next day the left arm and leg were found to be paralysed. The arm recovered after about five months; *the leg remained more or less useless for* a year, and weak for much longer, necessitating the wearing of supporting irons. The growth of the leg was also impaired, so that it is now considerably shorter than the right. Since the paresis passed away the patient up to the date of the present illness had always enjoyed good health with the exception of "a nervous breakdown" in the spring of last year. This, however, only seems to have lasted a week.

---

[1] Atlas de Laryngologie et de Rhinologie, p. 16.

The present illness followed a spell of extra work at book-keeping, owing to the absence of one of her fellow clerks. She came home one week end complaining of intense headache; this continued and on the following Monday she was seen by her own medical man, Dr. C. G. S. Leeds. He found her in a dazed, dreamy condition, every now and then crying out with the pain, which was not localised to any one spot but affected her whole head. She was given bromide, phenazone, and later aspirin, and appeared to improve somewhat, so that on the following Thursday the pain was decidedly better. On the Friday night, however, she had 11 convulsive attacks. The convulsions were limited to the left arm and leg, affecting the former more than the latter. They lasted from two to five minutes and apparently there was no complete loss of consciousness. On the Saturday morning there was a temporary cessation of fits, but they recommenced in the afternoon so that by the following day (Sunday) the patient had had another 20. By this time the convulsive movements were more violent and in some of the worst attacks there was complete loss of consciousness. Clonic movements of the muscles of the face and of the eyeballs also occurred. The patient was able to tell when a fit was about to occur and would cry out to this effect about a minute before the actual onset.

I saw her with Dr. Leeds, and as she was obviously going downhill and becoming more and more exhausted we decided to trephine the next morning. By that time (Monday) she had had another 29 attacks, and so frequent were they becoming that no less than four occurred whilst we were in *the house making our preparations. I turned down the usual* scalp flap and removed an inch and a quarter disc of bone over the right fissure of Rolando, having its centre about one and a half inches from the upper end of the fissure. I could find no depression or thickening of the bone, nor was the dura adherent to the skull. The brain bulged a good deal into the opening. The dura was incised for about three-quarters of an inch, without, however, throwing any further light on the case, and finally the scalp was sutured in position over the hole in the skull. The night following the operation the patient had altogether six fits, but these were not nearly so severe as her former ones. The next day she had none. That night again she had three very slight attacks. Since then up to the present time (six months) she has had none. The headache ceased the day following operation. The woman to-day is fit and fell. She has only been allowed to do easy work, but is very anxious to do more. She says that her head is much clearer than formerly and that she is much quicker *at figures and less easily fatigued* by them than before her attack.

The case is remarkable on account of the long period of time which elapsed between the initial injury and previous attack and the present one. Also on account of the benefit resulting from trephining, although nothing abnormal was found *at the time of operation.* I am not, of course, at the end of only six months so bold as to call the patient cured. Time alone will show that. I see no reason though why the fits should recur provided the woman can be induced to lead a placid, quiet life. Anyhow, the operation undoubtedly saved her life at the time.

ROYAL SOCIETY OF MEDICINE.

MEDICAL SECTION.

Arterial Blood-pressure Readings.

A MEETING of this section was held on April 27th, Dr. T. H. GREEN being in the chair.

Dr. O. K. WILLIAMSON said that observations by the method of circular compression were made on the leg and arm of the same patient in 21 cases of high arterial blood pressure. In all of the cases in which the arteries of the leg and foot could be felt these were found to be abnormally resistant and more so than those of the upper extremity; and in nearly all the cases there was also marked thickening in the arteries of the upper extremity. Ten cases of normal or low blood pressure, in which the arteries presented no clinical evidences of disease, were investigated in the same manner, so as to afford a basis of comparison. The observations were made on the calf and arm, the patient observed being recumbent, and the part of the limb on which the observation was made was at the level of the heart. Oliver's compressed air hæmomanometer was used with his 12 centimetre armlet. These observations showed that the resistance due to the arterial wall might markedly influence the readings, for the following reasons: 1. In the high blood-pressure cases the leg systolic readings were in nearly all cases markedly higher than the corresponding arm readings (average difference 32 millimetres), and the cases of highest blood pressure yielded distinctly greater differences than the cases of somewhat lower blood pressure. On the other hand, the leg diastolic readings in these cases were, on the average, practically identical with the arm diastolic readings (average difference less than 2 mm. Hg). 2. In the case of normal or low blood pressure the systolic arm and leg readings were found, on the average, to be identical (average difference less than 2 mm. Hg) 3. Inasmuch as the blood pressure in the leg could *not be higher than that in the arm (either* limb being at the level of the heart), and *seeing* that the influence of the tissues superficial to the artery might (when a sufficiently wide armlet was used) be neglected, it necessarily followed that the difference between the arm and leg readings could only be due to resistance of the arterial wall. 4. The conclusion that the abnormal condition of the arterial wall was a direct result of the increased blood pressure would seem to be inevitable, for the only obvious difference between the conditions to which the arteries of the legs and those to which the arteries of the arms are exposed in daily life was that, owing to the action of gravity, the former were subjected to greater hydrostatic pressure from a higher column of blood than were the latter.

Dr. GREEN said that it was very important to determine how far the pressure readings were influenced by the condition of the vessel wall, and on that point there seemed to be no definite agreement amongst various workers on the subject. A great deal had been done in the matter during *the last few years,* but much remained to be done. While waiting for that further information physicians had to be largely guided by their own unaided senses. When the blood pressure was largely increased and when the arteries were markedly thickened those facts were evident to the trained finger. There seemed to be danger at the present time of relying too much *on instrumental aids.* Even with the best instruments if there was not clinical skill physicians might fall far short of what they ought to achieve.

Dr. W. P. HERRINGHAM said that he had been making experiments on arteries that had been removed from the body 24 hours, and on arteries that had been three days out of the post-mortem room, being kept during those three days in a 1 per cent. solution of sodium chloride. He found that those arteries still gave in some cases high resistance readings just as other arteries did. The figures he obtained were 8, 13, 5, 4, 6, 12, 15, and 22 millimetres, showing that there was something in the artery itself quite apart from contractility. He had also been experimenting on simultaneous readings from the arm and leg, testing two places at the same moment, and his results confirmed those of Dr. Williamson.

Dr. T. D. SAVILL asked whether the author of the paper had compared the condition of the arteries in the lower limb with those in the upper limb in the cases quoted. In his (Dr. Savill's) prolonged investigation into the condition of the arteries in many old people at workhouse infirmaries he found that in most cases the leg showed a more advanced stage of degeneration than the arm. He had convinced himself that there was an initial stage of arterial hypermyotrophy or increase in the middle coat of the artery, prior to degeneration. He believed that the vital condition of the artery was of very great importance, and pointed out that the arteries after death were of different size to what they were during life.

Dr. LEONARD E. HILL said that he had not found evidence of the differences in pressure recorded by Dr. Williamson and substantiated by Dr. Herringham. He (Dr. Hill) laid stress on the importance of taking the readings in the two limbs simultaneously.

Dr. C. O. HAWTHORNE said that before they could accept the figures put before them they must be confirmed by other observers. He questioned whether that discussion on blood pressure was of great clinical importance. In addition to noting the element in the blood pressure due to the systole of the left ventricle they must appreciate the condition of the peripheral arterioles.

Dr. WILLIAMSON replied.

MEDICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on April 26th, Mr. C. B. LOCKWOOD, the President, being in the chair.

Dr. F. J. POYNTON and Dr. W. L. SCOTT showed three cases of Recurrent Familial Jaundice in a female, aged 22 years, in her sister, aged five years and eight months, and in a brother aged eight years and five months. The predominance of anæmia was striking in all three cases. Jaundice, though at times most definite, and in the eldest of the patients very striking, occurred only in definite attacks and could not be said to have been at all persistent. By daylight, however, the eldest had always an icteric tinge. In accord with the usual history of this type, the spleen was enlarged more in proportion than the liver; the varying size of the liver had been noteworthy. Dr. Scott observed that he had seen in each case an attack of deep jaundice with clay-coloured stools.

Mr. V. WARREN LOW showed a case of Congenital Dislocation of the Hip-joint treated by manipulation in 1905. The patient, a girl, who was now aged ten years, went to St. Mary's Hospital in 1905 with a congenital dislocation of the left hip-joint. Mr. Low saw her first in September, 1905, at the age of six and a half. The child then had the typical gait of a patient with a unilateral congenital dislocation of the hip-joint. There was 1½ inches shortening of the left limb. The upper end of the femur could be felt on the dorsum ilii and could be brought down to the level of the acetabulum. The limb could be freely moved in every direction except that of abduction. The mother said that the child could not walk more than half a mile without complaining of her leg and back, and that her peculiar gait always excited comment in the streets. The operation by manipulation (Lorenz) was performed in September, 1905. The child left the hospital a month later in plaster; this plaster was retained for six months. She was then readmitted to hospital, her leg was straightened under an anæsthetic, and a second plaster applied. This she wore for six months. Some stiffness and lameness remained for six or eight months after the second plaster was removed. There was now no shortening; the child walked without a limp and was able to run, skip, and walk considerable distances without fatigue.—Mr. T. H. KELLOCK emphasised the importance of recognising that the so-called "bloodless" reduction of Lorenz was a severe operation. He congratulated Mr. Low on the success he had achieved in the case before them.

Mr. KELLOCK showed a case of Traumatic Meningo-encephalocele cured after lumbar puncture and slight pressure. The patient was a child, aged three years. When nine months old she was admitted to the Hospital for Sick Children, Great Ormond-street, for a swelling on the head. The mother stated that the child was quite normal at birth and that there was nothing wrong with her until 14 days before admission, when during the mother's absence from the room the child fell on the floor, where she was found unconscious, convulsed, and of a blue colour. A swelling was immediately noticed on the side of the head, which the mother stated increased in size whilst she was watching it. On admission the child appeared to be quite healthy. A soft pulsating tumour of the size of half a Tangerine orange was situated over the centre of the left parietal bone; it was partly reducible on pressure and was felt to project through an uneven opening in the bone. The head was noticed to be rather flatter than normal behind, and the child had what was described as a "harsh cerebral cry." A day or two later the lumbar puncture was done and one and a half ounces of slightly turbid fluid were withdrawn. The tumour immediately disappeared and the opening in the bone could then be distinctly felt, with radiating fissures extending from it. Two days later the tumour had slightly re-formed, a pad with an elastic band was applied which controlled it, and this was worn for some little time after the child's discharge from the hospital. She had not ailed in any way since. There was no tumour to be felt, but the opening in the parietal bone still existed.

Dr. F. PARKES WEBER showed a case of Symmetrical Atrophy of the Hand Muscles with Cervical Ribs and a family history of cervical ribs. The patient was a girl, aged 13 years, showing nothing abnormal excepting in regard to the upper extremities. There was decided wasting of the thenar, hypothenar, and inter-metacarpal regions—that is to say, involving the intrinsic muscles—in the right hand, and to a lesser degree in the left hand. Faradic irritability was much reduced or altogether absent in the affected muscles of the right hand. The right hand was weaker and usually felt colder than the left hand; the dynamometer grasp in the right hand was 5 and in the left hand 15. There was no absolute anæsthesia, but there was decided hypo-æsthesia, especially to temperature, on the ulnar side of the right upper extremity, notably in the hand. The hypo-æsthesia to temperature involved the whole of the right hand, not merely the ulnar side; brachial blood pressure (Riva-Rocci method, with broad armlet) in the right arm was 90 mm. Hg.; in the left arm, 105 mm. Hg. The patient complained of occasional pain in the front of the right arm and forearm and sometimes in the hand. A skiagram by Dr. N. S. Finzi showed a small seventh cervical rib ([illegible] larged transverse process) on each side, but the one on [illegible] of the two, and its extremity ap[illegible] first dorsal rib. Palpation above did not reveal their presence. The history was that during the last two years the patient had occasionally suffered from pains of a sharp, shooting character in the right upper extremity, generally in the front part of the arm and forearm. The wasting in the hands was first observed two or three months ago. No similar muscular wasting had been observed in other members of the patient's family, but skiagrams (likewise taken by Dr. Finzi) showed the presence of similar seventh cervical ribs (or enlarged transverse processes) in her brother and sister. These were both younger (aged eight and 12 years respectively) than the patient, and the abnormal bony projections seen in the skiagram appeared to be less calcified and somewhat smaller; if they increased in size, as they might do about the time of puberty, atrophy in the hand muscles might then occur, although there was none at present. The father, aged 34 years, has been found, by skiagraphic examination, to be free from cervical ribs (or enlarged transverse processes), but no examination could be made in the case of the mother. They had only three children and all three of them, as already stated, had cervical ribs or enlarged transverse processes. The family history confirmed the observations of Theodore Thompson and others on the presence of seventh cervical ribs as a family peculiarity. The connexion of symmetrical atrophy of the intrinsic muscles of the hands with the presence of seventh cervical ribs had been explained by the writings of Thorburn, Lewis Jones, W. W. Keen, Hinds Howell, and Theodore Thompson. It appeared not to be so much the length as the shape, and especially the curvature, of the supernumerary rib on which the interference with the first dorsal nerve root (which in these cases gives rise to the atrophy of the hand muscle) depended. If, as Thorburn supposed, the cervical rib produced its effect by lifting up and stretching the brachial plexus, it could be understood that the grey matter of the spinal cord might sometimes be likewise affected so as to produce a partial dissociation of sensation resembling that which occurred in cases of syringomyelia. This might explain the supposed association of syringomyelia with the presence of seventh cervical ribs in some cases which had been reported. Muscular atrophy in the hands when due to the presence of cervical ribs occurred in girls or young women and was more frequently observed, or was more obvious, on the right side than on the left.—Mr. LOW asked what was the percentage of cases with cervical ribs in which nerve symptoms occurred, and Dr. LEONARD G. GUTHRIE pointed out that the ulnar side of the left hand of the patient showed a different temperature from that on the radial side, and said that that condition might be produced by some involvement of the first dorsal and the last cervical nerves.—Dr. WEBER, in replying, did not consider that a sufficient number of cases had been collected to determine the percentage for which Mr. Low had asked.

Dr. GUTHRIE showed a case of Progressive Muscular Atrophy in a man in which the onset had been gradual, lasting for seven months.

*Dr. G. WILLIAM HILL demonstrated direct vision laryngo*scopy on a female from whom a growth on one vocal cord had been recently removed by endoscopic surgery; tracheoscopy on a female with laryngitis and tracheitis; tracheobronchoscopy on a female with laryngitis, tracheitis, and asthmatic symptoms; and œsophagoscopy on a female with functional dysphagia.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 21st, Dr. P. Boobbyer, the President, being in the chair.—Dr. A. C. Reid read a paper on the Value of Ehrlich's Diazo Reaction to the General Practitioner. In this he pointed out the diagnostic value of the test in early cases of enteric fever. The disease must, however, have reached a certain stage before the reaction was present. When this stage had been arrived at the reaction was in his experience constant. It was also constantly present in miliary tuberculosis, but the differential diagnosis of typhoid fever was not so difficult from that disease as from febricula, gastric fever, abdominal influenza, and low broncho-pneumonia. The reaction did not merit the neglect it received from the general practitioner. As a negative test it occupied a foremost place, and as a positive reaction, when taken in conjunction with other signs, tests, and symptoms, it had considerable importance.—The President, Dr. F. H. Jacob, and Mr. O. Kentish Wright confirmed the value attached to this test by Dr. Reid.—Dr. A. J. Sharp, in opening a discussion on the Notification of Births Act, 1907, traced the changes brought about by the Act in the matter of still-births and exemption of the mother, and discussed the question as to how far a new duty had been laid upon the medical practitioner. Explaining the object of early notification as the first step in a movement for the reduction of infant mortality, he reviewed the various measures which had already been put into operation. Amongst these were baby-shows, bounties payable on the child attaining a certain age, systematic visitation by voluntary or paid workers, mothers and babies' "welcomes," the encouragement of maternal suckling, day nurseries, milk depôts, school instruction in hygiene, and general sanitary progress. Tracing various objections to the Act, that on the score of professional secrecy was the most serious and persistent, but this had no basis of support in law when a duty became public and statutory. Indeed, as regarded children not born in wedlock, they were above all others the ones who most needed the strong arm of the law to protect them. Their death-rate was at least double that of legitimate children.—Dr. S. E. Gill, continuing the discussion, emphasised the point that at the Nottingham Welcome no medical treatment of mothers or infants was attempted, but everything else that could be done in the way of encouraging the poor and inexperienced mother to feed, to clothe, and to tend her babe in a rational and hygienic way was done. In this way the more intelligent mother would act as a focus of knowledge and an example in her neighbourhood by which the general standard of infant hygiene and parental responsibility might be gradually raised. Indeed, the more aristocratic mothers might i directly become more disposed to fulfil their natural oblig tions to their infants, which at present were apt to be shelv in favour of the theatre or playing bridge.—The Preside pointed out that the Nottingham Welcome, although it h only been in existence about eight months, had alrea secured an average attendance of 200 babies per month. Mr. C. L. Rothera (Nottingham city coroner) agreed th the subject of infant mortality was one very vital to t health of the nation, and pointed out that the Childr Act, 1908, laid down medical aid as a necessity whi parents were compelled to provide for their children. I also drew attention to the elaborate system prevaili at Leipsic and elsewhere in Germany, by which children we examined weekly at a central depôt, so that any defe in the matter of health could be promptly detected ar dealt with.—The discussion was continued by Dr. J. Watso Dr. J. A. Waring, and Dr. W. Hunter.—Dr. W. Tibbl showed a Siamese, aged 19 years, the subject of Chron Œdema of One Hand and Forearm of one and a half year duration. The case had been carefully examined by M James Cantlie, who had considered the possibilities of i being due to local irritation, synovial inflammation, filari *ankylostomiasis, and angio-neuroses such as urtica* exaggerata, &c. A guess had been hazarded that it might b rheumatic, but there was no reason to attribute it to tubercl or specific disease. Blood examination had shown eosinophi corpuscles to be excessive, which rather suggested an inte tinal infection. Indicanuria also existed, raising a suspicio of disturbed proteid metabolism. Treatment by bandagin the hand in thick wool, sour milk internally, and a mixtu of oleum ricini cum oleo eucalypti had brought about som improvement, but a careful search in the stools had failed t reveal any parasite.—Dr. R. B. Purves (Lincoln) showed Myomatous Uterus with the Deflected Cavity resulting, ar Dr. Jacob showed microscopic specimens of Diplococci Intracellularis from a case of epidemic cerebro-spin meningitis.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.— meeting of this society was held on April 20th, D T. Jason Wood being in the chair.—Mr. W. H. Horrock showed: (1) Concretion from an Appendix which had bur through into the bladder and become coated with pho phatic deposit; and (2) Uterine Fibroid.—Mr. F. W. Goyd showed: (1) Sequestra removed from a case of Lumb Abscess; (2) a case of Serous Meningitis treated by drainag through the posterior fossa of the skull; and (3) a Brain wit Multiple Tumours, ? Nature.—Dr. Wood showed: (1) Carcinoma of the Breast with Enormous Mass of Glands in th Axilla; and (2) Uterine Fibroid.—Mr. J. Phillips and Dr. R. Honeyburne opened a discussion on Appendicitis. Mr. Phillips thought it best for the purposes of discussion to be somewhat dogmatic. He divided appendicitis into three types, the first of which he called the "simple type." In these cases, which were the mild ones, there were abdomina pain, tenderness in the right iliac fossa, a certain amount of fever, and quickening of the pulse. The treatment consisted in (1) absolute rest in bed; (2) no food of any sort nothing but water being allowed; (3) clearing out the lowe bowel by an enema; and (4) if necessary a simple carminativ mixture. As a rule these cases got well or they might pass o to the second type, the cases with a swelling in the right ilia fossa. These cases could safely be left till things quietene down. Operation was not advisable at first as owing t adhesions and inflammation it was usually a very difficult procedure. When operation was performed the appendix shoul always be sought for and removed. The third type (th gangrenous cases) were the cases in which the catastrophes occurred. Diagnosis was very difficult. It rested chiefly on facial expression and the rigidity of that segment of the rectus muscle underneath which the appendix lay. Immediate operation was the only treatment. The best incision was one just above Poupart's ligament. The pus should be mopped out and a gauze drain inserted. On no account should the peritoneal cavity be washed out.—Dr. Honeyburne said he was glad to hear that Mr. Phillips, although a surgeon, was yet so conservative in his ideas. He differed from him, however, in his method of treatment. The main question in any case was: How much was the peritoneum involved? And the main point in the treatment was to keep the inflammation of the simple adhesive variety. This was to be done by absolute rest for the inflamed part and not only should no food of any sort be given but the bowel must not be disturbed by enemata or any other method of evacuation When diagnosed morphine should be given in full doses and the patient kept under morphine until there was no more pain or tenderness *Operation was never required except* in the gangrenous cases when he quite agreed with Mr Phillips that *immediate* operation was the only chance Operation should be performed in the quiescent period by all means but not during the attack His own cases (250 in all) gave a *mortality of 2 per cent*—Mr Horrocks thought that in the early cases the application of leeches was distinctly useful He believed in calomel for the bowels Given in one quarter to half a grain doses every two hours and followed by an enema, he had seen excellent results from it Tympanites was relieved and the patient rendered much more comfortable In the second type where *the swelling was to the inner side of the iliac fossa*, careful watching was required, as the abscess was very liable to track down into the pelvis He quite agreed with Mr Phillips s incision in the gangrenous cases In those cases where appendicitis was closely connected with colitis the results were not good —Dr Rabagliati said that in his experience if left alone the abscess frequently *burst into the bowel and nature completed the cure* He wished there were some me [illegible] enous cases early so as to avert [illegible] they caused —Dr Wood said [illegible] with a swelling were always safe to leave and quoted instances from his own practice to back his opinion In these cases he thought the incision should be over the most prominent part of *the swelli* [illegible] very difficult—e g [illegible] logical thing was [illegible] In this way no harm was done to the cases classed as safe to leave, and the gangrenous cases would be taken early and given the best chance of life —Dr H J Campbell thought it was logical to operate as soon as diagnosed but not practicable He therefore advised treatment on the same lines as Dr Honeyburne but would give the morphine per rectum —Mr Phillips replied

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY —A meeting of this society was held at Manchester on April 23rd Dr J W Martin (Sheffield) the President being in the chair —A vote of condolence to the family of the late Mr Simeon Snell proposed by Dr D Lloyd Roberts and seconded by Mr R Favell was passed —Dr H Briggs (Liverpool) showed two specimens of Hæmatometra removed by the Abdominal Route In each case the retention of menstrual fluid was due to congenital atresia of the cervix The patients were unmarried women, aged 32 and 35 years respectively Microscopical examination of the uterine wall showed a great *excess of fibrous* tissue and an absence of glands in the endometrium —Dr A Donald (Manchester) read notes of a case of Bilateral Abscess of the Uterine Appendages occurring during Pregnancy Three weeks after spontaneous premature labour each abscess was drained extraperitoneally through an anterior colpotomy incision A marked improvement in the patient s condition immediately followed but two weeks later *symptoms of acute peritonitis appeared* On opening the abdomen a ruptured pyosalpinx was found and removed Since then the patient had made a steady recovery —Dr J H Willett (Liverpool) showed the specimen from a case of Cæsarean Section and Abdominal Hysterectomy for Carcinoma of the Cervix complicating a seven and a half months pregnancy The patient was a multipara aged 34 years Irregular hæmorrhage commenced at the end of the first month later the discharge became offensive The vagina was divided between clamps but no attempt was made to excise the pelvic connective tissue No enlarged glands were found The mother made a good recovery, but the infant died when four weeks old —Dr W Blair Bell (Liverpool) read the notes of a case of Acute Puerperal Sepsis with Thrombosis of the Ovarian Veins, which [illegible] h occurred 16 [illegible] ery complete [illegible] opinion that when septic thrombosis of the ovarian veins was diagnosed immediate ligation and excision of the ovarian veins should be practised —The President Dr Briggs Dr Donald, and Dr A W W Lea (Manchester) argued that operation in such cases was useless —Dr *Donald* read a note on the Use of Gauze Drainage in Certain Cases of Puerperal Sapræmia, in which retention of lochia occurs from sharp anteflexion of the uterus with sagging of the body Toxæmic symptoms, due to decomposition, generally arose on the eighth or ninth day or soon after Immediate improvement followed intrauterine *douching, but renewal of the retention and of the* symptoms was likely to occur This was best avoided by the use of a gauze drain

LIVERPOOL MEDICAL INSTITUTION —A meeting of this society was held on April 22nd, Mr T H Bickerton the President, being in the chair —Mr A A Bradburne read a note on Amblyopia Exanopsia He dealt with that type found in conjunction with high degrees of refractive error He considered the cause to be a cerebral defect and based his treatment on that theory He quoted one of his cases a boy aged 11 years, who had in six months special training *recovered vision from $\frac{6}{60}$ to $\frac{6}{6}$ or Jaeger 1 He considered that* want of success in treatment was due to the defect being a complex one, the visual act depending on several centres —Mr A Nimmo Walker advocated the whole time covering of the non squinting eye until the vision of the squinting eye became equal to that of the other This was possible in the majority of cases if taken early enough —Mr R O Dun read a note on Intussusception based on an analysis of 73 cases He argued in favour of irrigation followed if necessary, by immediate section Ether was always the anæsthetic used —Dr Hubert Armstrong discussed the paper —Dr F Wilson read a paper on the Serum Diagnosis of Syphilis Wassermann s and Noguchi s tests were described and their value was contrasted Using Wassermann s test 23 *results were positive out of 30 cases Of 20 controls 3 were* positive but in none of these could the possibility of syphilis be excluded With Noguchi's test 40 out of 52 cases were positive, also 3 out of 25 controls Out of 30 cases submitted to both tests 22 were positive with both, 4 were negative with both Two were positive with Wassermann s test [illegible] ative with [illegible] The opin [illegible] the more complicated of the two was the more trustworthy —Dr Ernest E Glynn referred to the fact that some cases of cancer growth give the Wassermann reaction and that guinea pigs' heart was as suitable an antigen as syphilitic liver The serum principle had been successfully employed in the diagnosis of typhoid fever and gonorrhœa

CHELSEA CLINICAL SOCIETY —A meeting of this society was held on April 20th, Mr A F Penny the President being in the chair —Dr J Blumfeld read a paper on the Nature of Sickness after Anæsthesia and the Best Means of Preventing or Treating It After a short summary of the physiological aspects of vomiting the different ways in which anæsthetic vomiting might be supposed to be caused were discussed and the influence of an effect upon the central nervous system was shown to be the most probable The characteristics of different types of patients and their immunity from or susceptibility to vomiting were considered and the influence of various drugs of saline enemata and injections of position after operation and of various kinds of operation were *discussed in their relation to the question* of sickness In the discussion that followed the President and a large number of the members present took part and many questions were asked to all of which Dr Blumfeld very *fully replied*

MANCHESTER PATHOLOGICAL SOCIETY —A meeting of this society was held on April 21st Dr W Milligan the President being in the chair —The President introduced a discussion upon the Pathology of Intracranial Suppuration limiting his remarks to suppuration of otitic origin The various micro and macroscopical pathways of infection were described and lantern slides of pathological specimens were shown upon the screen The pathology of extradural cerebral and cerebellar abscess was *discussed* in detail special reference being made to the organisms most usually found Purulent and serous meningitis was also fully described and reference was made to the occurrence of posterior basic meningitis in children as a sequel to suppurative labyrinthitis The pathology of sinus thrombosis and of perisinusal abscess was also discussed Various pathological preparations and photographs were shown

Reviews and Notices of Books.

The Principles of Anthropology and Sociology in their Relations to Criminal Procedure. By MAURICE PARMELEE, M.A. New York: The Macmillan Company. 1908. Pp. 410. Price 5s. net.

THIS volume, which belongs to the excellent series of handbooks published by the Macmillan Company under the general title of "The Citizen's Library of Economics, Politics, and Sociology," presents in a very interesting and lucid form the argument for the scientific revision of the methods of criminal procedure. Though dealt with in some detail in Ferri's "Sociologia Criminale" and in the works of Garofalo and other writers of the Italian school, this particular aspect of the problem of criminality has hitherto received less attention, at all events in the English-speaking countries, than its importance demands, so that Mr. Parmelee's study of the question, even if all his conclusions cannot be accepted, has the decided merit—not too common in these days of the making of many books—that it supplies a real want.

As is implied in its title, the work is written frankly from the standpoint of the positivist school of criminology; and it may be remarked that the author's enthusiasm for the principles of this school sometimes leaves him open to the reproach of accepting its theories in a rather uncritical spirit. This is most evident in the earlier chapters which deal with the biological factors in crime. In these chapters the author seems to go the length of taking Lombroso's doctrines as the basis for the whole thesis which he seeks to establish in his essay; and in this way he does himself a considerable injustice, for the critical discussion of the methods of legal procedure, which constitutes the really valuable part of the volume, is in fact quite independent of the precarious theory of "innate criminality." From internal evidence it would appear that the author is a lawyer, and it is probable that his lack of first-hand acquaintance with biological knowledge is mainly responsible for this over-zealous attitude which has led him to make such rash assertions as that criminal anthropologists "have distinguished between the different anthropological types of criminals" (p. 47). All this, however, is in reality much less material to his argument than the author seems to suggest, and the chief reason, indeed, for pointing it out here is to warn the reader against judging the book by what is its weakest and least important part.

The relation of the criminal to society is next discussed, and the basis of penal responsibility is investigated, the conclusion reached being that, whatever be the phases of its evolution in history, responsibility is now related solely to the principle of social defence. From this point of view criminal procedure is seen to be one of the measures of social defence and to be continuous with the others. It is the process by means of which the class called criminal is separated from the rest of society. Its fitness for this purpose, therefore, will depend on its adaptation to the characteristics of this class, so that, like the methods of penal discipline, it presupposes a knowledge of the biological and bio-social factors that have produced the given criminal act. The principle of individualisation is accordingly seen to apply as much to procedure as to punishment, just as, in medicine, diagnosis is related to treatment. This idea is further developed in two chapters discussing the individualisation of punishment and the principles of the criminal law. The next chapter deals with the forms of criminal procedure, of which two fundamental types are recognised—viz., the procedure of accusation, best exemplified in the English system, and the procedure of investigation, on which the French and most of the continental systems are based. In the succeeding chapters each of the different stages in these two forms of procedure is discussed in detail, and its merits and defects are considered from the point of view of psychological soundness. This critical review brings out very clearly the inadequacy of many of the existing methods of legal investigation, more especially as regards such points as the credibility of witnesses, the functions of the jury, and the selection of judges. In this connexion the admirable researches of Hans Gross on the psychology of evidence might have been more fully discussed.

In conclusion, the author summarises the modifications which he would desiderate in criminal procedure to bring it into accord with the modern scientific spirit. He advocates a much freer use of expert testimony, including the utilisation of the data of experimental psychology for the examination of witnesses. He would have judges better qualified than they are to estimate the force of such testimony by training them in psychology, normal and pathological, and in the other branches of knowledge which have to do with a complete study of criminal man. Such a training would include a sufficient course of clinical instruction in the prison and the lunatic asylum. In lieu of the present system of paid counsel he suggests that the prosecution and the defence should be conducted by trained advocates employed by the State. From these advocates the criminal judges would naturally be selected. This substitution of the expert for the amateur would entail the entire separation of the criminal and the civil bench, the criminal judge becoming a specialist in his own line. In consequence of his specialised training it would also be possible to associate a judge equipped in this way with the whole system of penal treatment, by imposing on him the duty of periodically revising sentences, which, of course, under the conditions contemplated would be indeterminate in duration. Finally, these reforms would include the abolition of the jury, which is, the author thinks, an obvious anachronism.

This brief summary of its contents will give some idea of the scope of Mr. Parmelee's work. It is inevitably open to numerous criticisms of detail, but in its broad lines it may be accepted as a just and well-balanced statement of the ideas which are now becoming current amongst scientific students of legal institutions, and which have already found a footing in the official teaching in several foreign countries. These ideas have, so far, had but little vogue in England, where there is an almost absolute indifference to the sociological aspects of crime on the part of those engaged in administering the criminal law, and it is on this account very much to be desired that so good an exposition of them should meet with the attention which it merits. It may be particularly commended as advocating in the practice of law the same principles which have contributed so powerfully to the progress of medicine.

Les Colloïdes en Biologie et en Thérapeutique. Le Mercure Colloïdal Electrique Par G. STODEL, Préparateur au Laboratoire de Physiologie de la Sorbonne. Paris: Vigot Frères. 1908. Pp. 282. Price 6 francs.

THIS book is divided into two parts. The first deals with recent work on the subject of colloids in general, or, more correctly speaking, as the author points out, with substances in a colloidal state, since many bodies are capable of existing in both crystalloid and colloid forms. This account is very interesting, calling attention, as it does, to a branch of physical chemistry which lies rather outside the range of most students and which seems to have been somewhat neglected in consequence until recent years. We learn that the colloid state consists in a condition of suspension in the form of excessively minute particles differing from the condition of solution in which a crystalloid body exists in a state of ionisation. By means of the ultra-microscope the particles in some colloid solutions can be seen; others, however, are too fine for even this instrument to reveal. These minute particles necessarily present an enormous area of surface in relation to their bulk, and the resulting surface-tension along with the electrical charges inherent in the particles accounts for many of the properties of colloids. As all living cells and membranes, as well as the fluids present in living organisms, are in a colloid state, it is clear that a knowledge of the phenomena presented by colloids in general is of importance to the student of biology. The author discusses the nature of diastases and of the different classes of immune bodies in this connexion. Some metals and metallic salts are capable of taking on a colloid form. The use of colloid silver in therapeutics is not new. The author has succeeded in preparing mercury in a colloid form and has tried it as a remedy for syphilitic affections. The record of his work here given, constituting the second part of the book, is interesting, but further research is necessary before we can admit the superiority of the new remedy over the usual preparations of mercury.

The book is clearly written and serves as a useful introduction to a study of the properties of colloids; as such we commend it—as a stimulant to further study of the subject rather than a complete account of the phenomena. It contains references to much recent original work. The print and paper are good, but there are a considerable number of typographical errors.

Hæmatological Atlas, with a Description of the Technic of Blood Examination. By Priv. Doz. Dr. KARL SCHLEIP, Scientific Assistant in the Medical Clinic, University of Freiburg-i.-B. English Adaptation of Text by FREDERIC E. SONDERN, M.D., Professor of Clinical Pathology, New York Post-Graduate Medical School and Hospital, Director of Clinical Laboratory, New York Lying-in Hospital. With 71 coloured illustrations. London: Rebman, Limited. 1908. Pp. 256. Price 42*s.* net.

THE plates of this atlas represent with remarkable fidelity and accuracy the appearances presented by the blood corpuscles in health and disease. The various forms of abnormal corpuscles are clearly depicted, and explanatory descriptions are afforded of each plate. With the exception of a few plates, delineating the appearance of unstained specimens, the illustrations represent the characters revealed by means of the Leishman modification of the Romanowsky method of staining. Uniform magnifications of 330 and 750 have been used. The plates are printed in colour on thick paper and are for the most part circular, with black margins, and represent very accurately the appearance of an ordinary field of the microscope. The plates are affixed to the pages of the book. The explanatory letterpress is printed in large type and the whole book is admirably produced. General instructions are given for obtaining blood for examination and for the preparation and staining of the dried films. The methods for examining a hanging drop of fresh blood and for enumeration of the corpuscles are also described.

The first plate is diagrammatic and is intended to illustrate the development of white and red corpuscles. All human blood cells are traced back to a parent form, and the plate is shown practically in the form of a developmental tree. It is, however, hypothetical and open to criticism in some of its details. The red corpuscle is traced back through the erythroblasts to a large mononuclear basophilic cell represented as one of the primary derivatives of the parent cell. From the derivative the transitional forms, the lymphocyte, the eosinophile, and the basophile cells are also derived, and some of the neutrophiles. Türk's irritation form is figured as a derivative of the lymphocyte. Plates II. and III. represent the general appearances of normal blood; Plates IV. to VII. depict the various forms of human white corpuscles. Very little distinction is made between the large and small lymphocytes; the transitional forms are carefully described and their special characters indicated. Türk's irritation forms are also represented; they occur in leucocytoses and in inflammatory processes. They resemble the large leucocytes and have a large nucleus poor in chromatin. Amitotic nuclear division figures are not uncommon. Other degenerative forms of leucocytes are also figured, including those showing the presence of vascular degeneration. The various leucocytoses, polymorphonuclear and eosinophilic, and lymphocytosis are represented in Plates VIII. to XIII. The appearance of numerous neutrophilic myelocytes in the blood in diphtheria is figured and their occurrence in that disease is described as an unfavourable prognostic indication. Plate XIV. is devoted to the erythrocytes, nucleated red corpuscles, and blood platelets.

The various anæmias are depicted in Plates XV. to XXII. Polychromatophilia and basophile granulation of the erythrocytes are well shown and the conditions under which they occur are enumerated. The features characteristic of various secondary anæmias, including that form due to hereditary syphilis, are also illustrated. Plates are given showing the appearances of the blood in the primary anæmias, chlorosis, and pernicious anæmia.

The various forms of leukæmia form the subject of Plates XXIII. to XXXVII., and the different forms of corpuscle are carefully differentiated and liberally illustrated. Useful outline diagrams are given of the more important specimens reproduced and the names of the various corpuscles are clearly indicated. The blood changes associated with tumours of the bone marrow are represented in Plates XXXVIII. to XL., including carcinoma, sarcoma, and leukosarcomatoses, the latter being a condition described by Sternberg. The concluding section, consisting of Plates XLI. to XLV., is devoted to blood parasites. Various forms of the malarial organism are shown and one plate of the human trypanosome.

The atlas may be taken to present very well the ordinary changes seen in the blood in certain diseases and should be of value to those practitioners who are interested in the hæmatological investigation of their cases and are unable to work out their specimens in a laboratory, for it should enable them to identify the various types of corpuscles. In the preface it is claimed that "an accurate picture of characteristic changes is often better than a detailed description or an imperfect specimen." The atlas should certainly enable the practitioner to interpret the results he obtains with films from actual cases.

The Cell as the Unit of Life, and other Lectures. (An Introduction to Biology.) By the late ALLAN MACFADYEN, M.D., B Sc. Edin. Edited by R. TANNER HEWLETT, M.D. Lond., F.R C.P. Lond., D P.H. London: J. and A. Churchill. 1908. Pp. xvi.–381. Price 7*s.* 6*d.* net.

THE courses of lectures included in this volume were delivered by Dr. Macfadyen at the Royal Institution, London, during his tenure of the office of Fullerian Professor of Physiology from 1899 to 1902. Dr. Hewlett has done his work as editor excellently, but in his short introductory biographical notice of Dr. Macfadyen he has been misinformed as to the names of one at least of Dr. Macfadyen's teachers in Edinburgh—viz., "Sir Croom Halliday." Dr. Macfadyen did excellent work in the domain of cell life and bacteriology, and all too soon, at the early age of 46 years, he fell a victim to his zeal in research, accidentally infecting himself with typhoid and Mediterranean fevers, from which he died in March, 1907.

The following statement shows the scope of these lectures. "The Cell as the Unit of Life" is dealt with in five lectures (March and February, 1899); "Cellular Physiology" in six lectures (1901); to "Recent Methods and Results in Biological Inquiry" (1902) are allotted three; and to "Toxins and Antitoxins" (April, 1899) four lectures. A Friday evening lecture, "On the Effects of Physical Agents in Bacterial Life" (1900) completes an interesting series. The lectures give a clear, straightforward, very readable account of cell life, and form an admirable introduction to the study of biological problems associated with the cell in all its aspects as a living and productive organism in its morphological, structural, and chemical relations. Necessarily there is a certain amount of overlapping where the theme is cellular from start to finish, and where the simplicity of thought and diction are very marked it must be recollected that the lectures were no doubt well adapted for the audience at the Royal Institution. In the first course protoplasm and all that belongs to it is dealt with, including cell life in general; a short account of the ferments is given, and the responses of protoplasm to stimuli are explained. The second course deals in a general and interesting manner with enzymes, and fermentations and their importance both in the arts and in science, as well as their relations to the germ theory of disease. The course on methods of biological inquiry is a short one, and treats of, amongst other subjects, nitrification, phosphorescence, toxins, agglutination, and life at low temperatures. As bacteria retain their life at the temperature of liquid air and become extremely brittle this led the author to triturate them at this low temperature, and in this way a pure cell plasma without an admixture of sand and Kieselguhr was obtained. It was shown that the typhoid bacillus contains within itself a toxin and in this way devitalised intracellular toxins were obtained from bacteria. As the lectures on toxins were delivered in 1899 the editor has added a few notes to the methods outlined in the lectures.

The whole is pleasantly written and gives an admirable summary of cell life which could be understood by a lay audience such as that which attends the discourses of the Fullerian professor for the time being at the Royal Institution. There are appended a glossary and a list of Dr. Macfadyen's publications.

The Struggle against Tuberculosis in Sweden. Edited by STURE CARLSSON, M.D. With illustrations. Issued by the Swedish Government. Stockholm: Central-tryckeriet. 1908. Pp. 200.

AMONG the progressive nations of Europe seeking to combat tuberculosis with scientific precision Sweden occupies a foremost place. Something of Swedish methods and measures have already been detailed in this journal.[1] We therefore gladly draw attention to the admirable collection of studies prepared by a representative Swedish committee and dedicated to the International Tuberculosis Congress recently held in Washington. The work is one of which Sweden may well be proud. It should certainly be carefully studied by those in this and other countries who are desirous of seeing anti-tuberculosis work organised on rational lines. It is a record of medico-sociological experience and scientific experiment rich in suggestive value and amply testifying to the benefit of coördination and coöperation of medical, social, economic, and humanitarian effort and service. Dr. Bertil Buhre, the able secretary of the Swedish National Anti-Tuberculosis Association, describes the far-reaching influence and benefits wrought by this truly national body. Other contributions of great value follow, detailing the results of anti-tuberculosis work in various parts of Sweden. Dr. John Tillman of the Österasen Sanatorium, contributes a thoroughly common-sense essay on Sanatorium Treatment at Home; Mrs. T. Gelhaar describes the charity stamps which have proved so popular and successful a means for raising revenue; Dr. Emil Wadstein of the Hessleby Sanatorium writes of King Oscar the Second's Jubilee Fund and its service in establishing and administering public sanatoriums for Sweden's consumptives; Dr. C. E. Waller furnishes notes on physical methods of diagnosis; Dr. Sture Carlsson, of St. Göran's Hospital at Stockholm, deals with the various institutions existing for the treatment of tuberculosis in Sweden; and there are other articles of clinical and pathological interest. We have, however, furnished sufficient proof to substantiate our opinion as to the value of this notable volume. No serious student of the tuberculosis problem can afford to be neglectful of such a record of Scandinavian thought and enterprise. The volume is handsome in appearance, well illustrated, excellently printed, and the English, although occasionally quaintly expressed, is generally clear and attractive. All concerned in the production of the work are to be congratulated.

La Pratique des Maladies des Enfants (Diagnostic et Thérapeutique). Secrétaire de Rédaction: R. CRUCHET. Fasc. I. Introduction à la Médecine des Enfants: Hygiène, Allaitement, Croissance, Puberté, Maladies du Nouveau-né. Par A.-B. MARFAN (Paris), J. ANDÉRODIAS (Bordeaux), et RENÉ CRUCHET (Bordeaux). Paris: J. B Baillière et Fils. 1909. Pp. 476. Price 10 francs.

THIS is the first fasciculus of a comprehensive work on diseases of children, to which no less than 24 authorities from the different French schools are to contribute, the general editorship being in the hands of Professor Cruchet of Bordeaux. The editor points out the increasing importance now attached to care for the health of the *young* and notes that the *problems most urgently calling for treatment* differ somewhat in different countries. Thus in France *the* fall in the birth-rate is most disquieting, in England the mortality which occurs in early infancy, and in Germany the incidence of nervous affections and even of suicide among children of a rather later age. He claims that the study of children's diseases is a specially French branch of medicine, and if the other volumes of this work maintain the standard set in the first we shall be inclined to admit the truth of the claim. The articles here set before us are most interesting and stimulating. The first 100 pages are occupied by a section written by Professor Marfan, dealing with general considerations on the peculiarities of the disorders of children, and embracing such points as the bacteriology of the infant's alimentary canal, the effects of boiling on milk, and the causation of some of the special forms of wasting or athrepsia met with in infants. The second section, occupying the greater part of the volume, is by Professor Andérodias, and is devoted to the maladies of the new-born child, malformations and obstetrical paralyses, hæmorrhagic conditions and infections, and above all the detailed consideration of artificial feeding. A short chapter on the disorders of later childhood by Professor Cruchet is notable for its advice as to the moral training of children so far as their desire for information on sexual matters is concerned.

Different countries are distinguished by different points of view in matters of science no less than in literary or moral spheres, and it is most useful for all physicians to endeavour to correct any onesidedness in their views by studying those of their colleagues in other parts of the world. For this reason especially, no less than for its general excellence, we cordially recommend the study of this book to all who are interested in the diseases of children. It is clearly and *pleasantly written by men who are experts in their subjects,* and should constitute an authoritative text-book of modern French practice in this department.

---

[1] THE LANCET, July 18th, 1908, p. 189.

Die Neurologie des Auges. By Dr. H. WILBRAND, Ophthalmic Surgeon and Dr. A. SAENGER, Neurologist in St. George's [illegible] e Path- [illegible] 1909. Pp. 463. Price 18 marks.

Qu'allaient-ils faire dans cette galère? Wilbrand and Saenger's "Neurology of the Eye" continues to pursue its long and tortuous path, but the goal seems as far off as ever. After bulky volumes devoted to the neural pathology of the lids, lacrymal apparatus, and cornea we were plunged into a long disquisition on the anatomy and physiology of the optic paths and centres, in which the authors considered it their duty to include a comprehensive account of what is usually known as physiological optics. "*Revenons à nos moutons!*" said the authors, this lengthy excursion into pure physiology over, so they gave us 600 pages on the general diagnosis and symptomatology of defects of vision. Alas, their pesky conscience seems to have troubled them again. The retina is part of the nervous system; therefore, every abnormal retinal condition belongs to the neurology of the eye, so they make a valiant plunge into pure ophthalmology. "It may well seem surprising to many," they say, "that we should have devoted so much space to the pathology of the retina." We agree. But here it is, and on the whole it has been done quite well, though not so well as the purely neurological parts. They are more at home with their sheep than with their goats. It is, perhaps, sufficient to say that the half volume (463 pages) deals with nearly all the retinal disorders which are usually treated in an ordinary text-book of ophthalmology. We prefer to confine our criticism to the one definitely neurological section, one of 20 pages on amaurotic family idiocy. It betrays the tendency which has been shown before by others to obscure this peculiarly characteristic disease by including under the same designation other conditions which bear only a feeble resemblance to it. Thus, undue prominence is given to Vogt's papers on the so-called juvenile form of amaurotic family idiocy, which really belongs to an entirely different class. The bibliography given of the disease is by no means exhaustive and is vitiated in the same manner by the inclusion of cases having only an indirect bearing upon the subject. Wilbrand and Saenger's "Neurology of the Eye" is a most valuable work, but we would urge the authors to confine themselves more accurately to pure neurology and to venture into the domains of physiology and ophthalmology only in so far as is essential for the thorough elucidation of their special subject.

LIBRARY TABLE.

Modern Methods of Sewage Disposal. By W. H. TRENTHAM and J. SAUNDERS. London: The Sanitary Publishing Company. 1909. Pp. 60. Price 2*s.* 6*d.* net.—This is a simply written little book, intended primarily for the use of members of local authorities and their officials. The authors state that they have had 20 years' experience in the design, construction, and practical management of sewage works, and they deal with such matters as sewer construction, the various methods of sewage purification, and finally they have a chapter on "The Ideal Method of Treating Sewage." Their own scheme, which they allow falls short of the ideal, which at present is impossible, is described. House refuse and the screenings of the sewage are dealt with in a destructor which raises steam which again is converted into electrical energy. The sewage proper is dealt with in aerobic slate beds and filter beds. The book, of course, does not go deeply into the subject but as an *introduction to the study of a most important part of public* health it will be found useful.

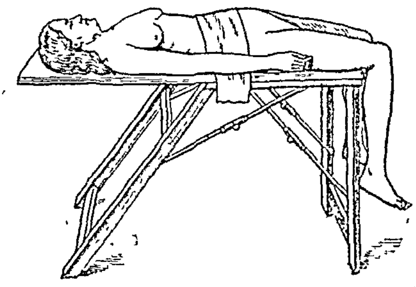
JOURNALS AND MAGAZINES.

The Quarterly Journal of Medicine. Edited by WILLIAM OSLER, J. ROSE BRADFORD, A. E. GARROD, R. HUTCHISON, H. D. ROLLESTON, and W. HALE WHITE. Vol. II. No. 7. April, 1909. Oxford: At the Clarendon Press. Subscription price, 25*s.* per annum. Single numbers 8*s.* 6*d.* each.—This number contains the following papers: 1. Bronchiolectasis in Children, with reference to the Condition known as Honeycomb Lung, from a clinical standpoint, by Ernest Leach Five cases are described and the clinical features are analysed. The morbid anatomy and causation of the condition are also discussed. 2. Vaso-dilators in High Blood Pressure, by Edwin Matthew. By means of hæmomanometric observations certain conclusions are drawn as to the individual and relative action of *nitrites* and *organic nitrates,* and various recommendations are given as to the dosage of the therapeutic nitrites. 3. Further Researches on the Etiology of Endemic Goitre, by Robert McCarrison. Evidence is offered of the experimental production of goitre by the administration of suspended matter filtered off from waters known to produce goitre in Gilgit. Boiling the material deprives it of its power of inducing goitre. The incubation period of experimentally produced goitre is from 13 to 15 days, and the disease can be cured by the administration of internal antiseptics. 4. Infective Endocarditis, by Thomas J. Horder, with an Analysis of 150 Cases and with Special Reference to the Chronic Form of the Disease. This paper contains a valuable account of the various forms of infective endocarditis, and special attention is given to the bacteriology and to the treatment. 5. Acidosis: a Critical Review, by Edmund I. Spriggs, giving an interesting summary of the conditions leading to acidosis and of its occurrence in association with diabetes and certain toxæmic states occurring clinically.

New Inventions.

A NEW OPERATING TABLE.

A new portal [illegible] table made by Messrs. Allen and Hanburys, [illegible] to the specificatior [illegible] ow. It has many advantages and has been found by Dr. Berkeley to be extremely useful. It can be opened and fixed in position or folded up again in less than one minute, and it has

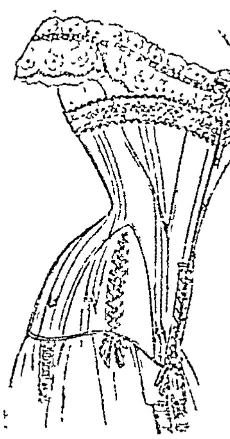


been tested to take patients weighing up to 20 stones. The table is made of oak, the measurements being: length, 48 inches; width, 21 inches; height, 32 inches. The weight is 31 pounds. *It fulfils perfectly the objects for which it* was designed and will be found equally useful for operating either in the Trendelenburg or the lithotomy positions.

Unlike many operation tables on the market which profess to give the correct Trendelenburg position and fail to do so, this table, Dr. Berkeley considers, is in this respect perfect, and the mechanism by means of which the top is raised and lowered is very simple and works very easily. On being practically tested this table was found to answer the purpose for which it was constructed, but we suggest that when used care should be taken to interpose a well-folded blanket between the edge of the table and the popliteal space.

A HYGIENIC CORSET.

We are often pressed to express an opinion upon some departure from the usual forms of wearing apparel, but seldom find ourselves able to say much in favour of the modification, which even though recommended to us by members of the medical profession fails commonly in fulfilling the claims made for it. A combined corset and surgical belt, however, which has been submitted recently for our inspection by Mrs. Morison of 26, South Molton-street, London, W., deserves to be brought to the notice of our readers. It provides a comfortable and adequate appliance for many invalids and for others who, while hardly invalids, are recommended some form of surgical belt. By a skilful method of cutting the corset and belt all in one piece the advantages of a surgical belt are secured and a suitable apparatus is furnished applicable in cases requiring abdominal support. This combined corset and surgical belt is so constructed, the inventor claims, that it not only gives abdominal support but leaves the ribs and diaphragm free from compression, so that respiration is not interfered with. We made trial of the corset with particular attention to this matter, and in our view the breathing is not incommoded by any pressure which the lower or "belt" part of the appliance may exercise on the abdominal planes. The corset is, of course, "cut" smaller in the groin than in the abdomen, so that when the front and sides are laced an upward pressure is given to the abdominal contents and the wearer is able to assume the erect posture with greater comfort and to take valuable exercise much earlier after an operation. An inspection of the accompanying illustration will show how this corset is well adapted to replace the surgical belt in many common conditions. The technical name of the material of which the corset is made is "tricot," which we should describe as a sort of clinging stockingette possessing great elasticity without, however, containing elastic. This corset has been successfully employed for the relief of troublesome symptoms during and after pregnancy and has been found efficacious in cases of hernia, moveable kidney, and weakness of the spine. In the treatment of pendulous belly the advantages of this corset are self-evident, and by suitable alterations it can be made applicable for other conditions.



Combined corset and surgical belt.

BRITISH MEDICAL BENEVOLENT FUND.

At the April meeting of the committee 23 cases were considered and grants amounting to £204 5*s*. made to 20 of the applicants, two cases being passed over as unsuitable for help and one postponed for further inquiries. Appended is an abstract of the cases relieved:—

M.R.C.S., L.R.C.P., aged 31 years. Has been incapacitated for some time by ill-health and exhausted all his resources; is now better and able to undertake a little light work, but requires immediate help to purchase a few necessary articles of clothing, &c. Voted £2 5*s*.

Widow, aged 38 years, of M.B., Ch.B. Glasg. Lost her husband soon after marriage and is at present dependent on relations who can ill afford to help. Proposes to train as a maternity nurse and friends promise to pay part of the expenses. Voted £5 conditionally upon the balance of the money being found.

Widow, aged 60 years, of M.R.C.S. No income; endeavours to support herself by letting lodgings; children only able to give very slight help. Relieved three times, £34. Voted £18.

Widow, aged 61 years, of M.R.C.S. Quite unprovided for at recent death of husband, whose means were exhausted by a two years' illness. No children. Voted £12.

[illegible] M.R.C.S. No means; has been given a [illegible] return for services, but fears she will soon [illegible]

[illegible] late M.R.C.S. No income; used to act as housekeeper to a brother, and after his death qualified as a maternity nurse, but now obtains so few cases that she is obliged to apply for help. Voted £12.

Widow, aged 56 years, of L.R.C.P., L.R.C.S. Edin. No income, and since husband's death 20 years ago has supported herself as children's nurse, &c., but has recently been incapacitated by a serious illness which has exhausted her small savings. Voted £12.

M.R.C.S., aged 70 years. Until a few months ago was in practice but has recently undergone an operation for gangrene and is now quite incapacitated. Slight help from children. Voted £18.

Daughter, aged 59 years, of late M.R.C.S. Allowed 5*s*. a week by friends and earns about the same amount by needlework. Relieved twice, £30. Voted £12.

Daughter, aged 59 years, of late M.R.C.S. Is given a home in return for services but requires help for dress and other unavoidable expenses. Health very indifferent. Relieved seven times, £108. Voted £12.

Daughter, aged 48 years, of late M.R.C S. Is a confirmed epileptic and consequently unable to follow any occupation. Dependent on a brother-in-law who can ill afford to help and receives £10 a year from the National Hospital for the Paralysed and Epileptic. Relieved twice, £22. Voted £12.

Daughter, aged 43 years, of late M.R.C.S. For many years past has been obliged to nurse her recently deceased mother, an annuitant of this Fund. Hopes now to support herself by letting rooms, but requires a little help meanwhile. Relieved once, £5. Voted £5.

Daughter, aged 66 years, of late M.R.C.S. [illegible] teaching for 43 years, but is now unable to d[illegible] and sight failing; no means; earns a few [illegible] knitting. Relieved once, £12. Voted £12.

Widow, aged 62 years, of L.F.P.S. Glasg. Only income £10 a year from a charity. No children. Lets rooms, but has great difficulty in obtaining lodgers, and is in very bad health. Relieved six times, £60. Voted £10.

Daughter, aged 60 years, of late M.D. Aberd. Has given music lessons for nearly 40 years, but finds increasing difficulty in getting pupils, and is in a very feeble state of health. Relieved twice, £20. Voted £10.

Widow, aged 49 years, of L.R.C.P., L.R.C.S. Edin. No income, dependent on two sailor sons, both at present out of work. Relieved five times, £51. Voted £12.

Widow, aged 61 years, of M.R.C.S. Eng. No income, slight help from friends; a son sends a few shillings occasionally. Is quite incapacitated by permanent ill-health. Relieved three times, £36. Voted £12.

Daughter, aged 53 years, of late M.R.C.S. Is unable to earn a living and dependent on three sisters who have to support themselves. Voted £5.

Daughter, aged 25 years, of late M.R.C.S. Health quite broke down after nursing her mother through a long illness ending in death, and for some months past has been an inmate of different institutions. Relieved once, £6. Voted £6.

Widow, aged 66 years, of L.R.C.P. Lond. No income; unprovided for at husband's death about 20 years ago and has supported herself by a boarding house, but now finds it impossible to make both ends meet. Relieved three times, £36. Voted £12.

Contributions may be sent to the honorary treasurer, Dr. Samuel West, 15, Wimpole-street, London, W.

Queen's College, Belfast.—The following prizes for the session 1908–09 were awarded at the class examinations in medicine recently held:—Zoology: J. B. Lyle, N. Beattie, W. S. Lynd, B.A., and T. Walker. Chemistry—Senior: W. G. Glendinning. Junior: J. M. Bell, A. K. Macbeth, and W. M'K. H. M'Cullagh. Practical chemistry—Senior: J. Greer. Junior: J. G. Wilkin, C. L. Gaussen, S. R. Armstrong, J. R. Henry, A. M. Glendinning, and J. Lyons. Chemical laboratory: W. G. Glendinning. Anatomy—Senior: F. Crooks and T. D. Graham. Junior: J. H. Beverland, S. R. Armstrong, and W. M'N. Walker. Practical anatomy—Senior: A. Hegarty, S. R. Armstrong, T. D. Graham, H. W. M'H. Wallace, C. L. Gaussen, F. Crooks, and J. R. Henry. First year: J. M'I. Gibson, W. M'N. Walker, and N. C. Graham. Physiology—Senior: R. J. M'Connell, F. Crooks, and M. J. M. Stewart. Junior: W. J. Hunter, B.A., S. R. Armstrong, J. H. Beverland, C. L. Gaussen, and W. M'N. Walker. Practical physiology—R. J. M'Connell and W. M. O'Farrell. Practical histology: J. H. Beverland, L. D. I. Graham, S. R. Armstrong, W. M'N. Walker, M. J. M. Stewart, J. Lyons, and J. J. H. Mitchell. Special prizes for histology demonstrations—J. H. Beverland, S. R. Armstrong, and H. W. M'H. Wallace. Materia medica—F. Crooks and J. A. Hutchinson. Medicine—R. A. Kerr and A. W. Connolly. Midwifery, gynæcology, and diseases of children—H. Black, C. J. Simpson, W. A. Anderson, R. A. Kerr, S. E. A. Acheson, and M. C. Irwin. Surgery: H. Black, S. E. A. Acheson, and B. M'Cullough, B.A. Ophthalmology and otology—H. Black and C. J. Simpson. Sanitary science—H. Black, C. J. Simpson, R. A. Kerr, and S. E. A. Acheson.

THE LANCET.

LONDON: SATURDAY, MAY 1, 1909.

Academic Distinctions.

HAMLET, it may be remembered, was at school at Wittenberg, but it may perhaps be assumed, even with a near approach to certainty, that the kingdom of Denmark possessed no University at the time, for if it had done so it is inconceivable that POLONIUS should have omitted to include the possession of a distinction thence derived among his various recommendations to the departing LAERTES, or that he should have failed to recognise to how great an extent the judgments of mankind are often dependent upon labels rather than upon the properties which these labels are supposed to indicate. We do not intend in the least degree to undervalue university distinctions; but we cannot close our eyes to the fact that universities are becoming numerous, and that the desire to possess an academic title, which has long been prevalent in the medical profession, may, perhaps, be in progress of being gratified at the expense of some diminution in the value of the result; not because the universities are willing to lower their standards, for the contrary obtains, but because the demands of medical education are not such as to be entirely satisfied by the curriculum which is naturally crowned with a degree. The fact of being a Doctor of Medicine or a Master of Surgery should undoubtedly carry with it a reasonable presumption that the bearer is a man exceptionally fitted to cope with medical or with surgical emergencies; but we very much doubt whether the facts will invariably support the presumption, or whether the tests to which candidates for medical or surgical academic honours are required to submit are always, or necessarily, of a kind to indicate real proficiency in the application of knowledge to the events of life or to the control of disease. The tests in question are usually such as to facilitate the display of what may be called "cleverness," quickness of faculty in the production of small change for the gold of knowledge; and the power of passing through them in a manner satisfactory to examiners, and so as to acquire the right to assume some distinctive label, although usually indicative to say the least of a certain degree of self-control and self sacrifice, is none the less to some extent dependent upon pecuniary means and upon perseverance, and is at best a very imperfect criterion of the special aptitudes, the resourcefulness, the courage, and the presence of mind which combine to render the practitioner who is endowed with them a tower of strength in the sick room, and which qualify him to exercise professional authority in the gravest emergencies. It is the business of the stage to "hold the mirror up to nature," and SHERIDAN KNOWLES was fully justified in rendering FONDLOVE'S proficiency in the *Ars Amatoria* of OVID but slenderly helpful to him in the conduct of his actual courtship of the lady of his affections. We believe that a power of answering difficult questions with facility and smoothness may sometimes be of as little value to a practitioner; and we fear that the growing tendency to confine great professional facilities, hospital appointments and the like, to candidates of high academic standing may not, in the long run, prove to be of unmixed advantage either to patients or to the profession.

The recent republication by Sir ALMROTH WRIGHT, under the title of "Studies in Immunisation," of the many papers in which he and his fellow workers have from time to time set forth their results in the direction of vaccine therapy, has afforded to the distinguished author an opportunity, of which he has not been slow to avail himself, of expressing his manifestly deep conviction that the contemporary medical practitioner, though he be graduate with honours, has not as a rule received a sufficient scientific training to render [illegible]s will be [illegible] present medical curriculum, and the length of time required by the average medical student before he can obtain a place upon the Medical Register. Sir ALMROTH WRIGHT tells us that in every other department of practical life, in shipping, for example, or in railways, a much higher standard of responsibility is enforced than in medicine, and he predicts that this laxity will not be indefinitely permitted. "The higher standard of responsibility, which is enforced everywhere else in civilised life, will also be enforced in medicine when we have shaped it into something more like a scientific profession." .... "So long as we as a profession go on hankering after the impossible, so long as we demand of every new therapeutic method that it shall, after the manner of a magic wand, achieve the marvellous with little labour, and that it shall give its best results even when it is applied in an absolutely blind empirical manner, so long will disillusion continue to dog the steps of medicine. There will be an end, once and for all, of such clamouring for the moon as soon as science shall have imported order and measure into our expectations." Many other passages of like kind are dispersed throughout the volume, and they all express a profound conviction of the utter inadequacy of the "rule of thumb" practice which many observers believe to be forced upon our students by the exigencies of the present education. If the existing degree of recognition of the value and importance of the work of the clinical laboratory as a guide to the daily work of the practitioner has scarcely at all led to a definite increase in the direction of endeavours to qualify him to undertake such work for himself, but rather to a passive acquiescence in its performance by a few persons as a sort of specialty, the professors of which must be consulted by practitioners when the latter require guidance which the generally familiar forms of investigation are inadequate to give, our scientific progress in the profession as a whole is not as great as it is believed to be. The tendency of such a course must manifestly be to place a gulf between the investigator and the practitioner, and to induce the latter to rest upon laboratory conclusions blindly, and as by rote, without any reasoned endeavour to bring them into continuous harmony with the facts observed at the bedside. We believe that never before were there so many practitioners striving to keep abreast with the rapidly developing knowledge of pathology and therapeutics; but the equipment of the modern medical man is a very elaborate one, and he who falls behind soon comes to occupy a hopeless position in the race. If it be admitted, as we think it must be, that the advances of modern medicine are to be looked for, during the next few years at least, chiefly in the direction of laboratory work, or of what is commonly understood by "research," we ought to expect in medical education as it is now conducted, even when academic honours are at its goal, a definite tendency towards the production of scientific men. The aim of the curriculum should be to qualify all members of the medical profession either to conduct laboratory investigations for themselves, or fully to appreciate their value when conducted by others. The question necessarily arises how this condition of things may be reached—how medical education may be so modified as better to prepare those who undergo it for the class of duties which, at no distant period, they will inevitably be expected to perform. The range of study is large and the time at the disposal of the student is all too short. The universities, old and new alike, are striving to give to science the practical attention which should ensure the production of scientific medical practitioners, and the same may be said of the various corporations, but even so it is difficult to see how the average man is to find time to master the chemical, physiological, or pathological investigations upon which, in the long run, we must rely for the cure of individual disease and for the preservation of the health of communities. Certainly we do not find that those who have achieved the greatest academic distinctions necessarily excel as practical men, while it must be admitted that those who do so may in some instances find it difficult to appear before the public in their right position, in consequence of not having obtained the label which carries conviction to the public mind. And all this may be read as showing that the medical curriculum is overloaded.

We have heard it suggested, and argued with considerable weight, that the medical profession is not likely to be completely qualified for the discharge of its duties until the scheme of its education is completely remodelled in a fashion analogous to that which obtains for the Royal Navy, and until the future medical man, like the future naval officer, is set apart from his very boyhood, and is compelled to devote himself continuously to studies bearing upon the work of his intended calling. The difficulties in the way are threefold, the first of them being that the public, as at present advised, are not disposed to reward skill in medicine with sufficient liberality to induce parents to incur heavy cost in qualifying their sons to attain it; the second being that the suggested isolation from students of other classes might tend to diminish capacity for dealing with the many personal and private questions with which the life of a medical practitioner becomes so inextricably blended. In the third place, who is to pay those who undertake this prolonged and costly scheme of education? We doubt whether any one of these objections is insuperable. It can scarcely be doubted that a definite improvement in the general character of medical work would be followed by a corresponding elevation of the standard of remuneration accorded to it; and we do not know that the naval officer is less conspicuous than his subordinate, the proverbially "handy man," in his power of mental adjustment to the conditions in which he is called upon to work. But we have to regard the idea, at any rate for the present, as visionary. All that we can yet hope for is the gradual lengthening of the statutory time of the medical curriculum, and the introduction of simplifying modifications into the examinational schemes, as partial remedies for the existing unsatisfactory conditions. In particular, any signs of effective union between the universities and the corporations will be of promise, as tending to place all qualified men on a more practical footing of equality, and so allowing the best of them to come to the front by the merits of their professional work.

◆

The Position of Plague in India as Illustrated at the Bombay Medical Congress.

IT is now 12½ years since plague first appeared in Bombay, and during this period it has caused approximately six and a half million deaths. So far, in 1909, the death-rate has been low, but too much stress must not be laid upon this, as the rises in mortality which have occurred from time to time during the long epidemic have had no distinct causes. The cynical might say that plague in India has not been without its advantages. Before its advent the Government of India were engaged in discussing what was considered to be one of the great problems of the future—viz., how to relieve India of a surplus population through emigration. That problem has certainly been solved in some districts. Medical science has also benefited indirectly as well as directly, for the vast plague mortality stirred public opinion, so that a Royal Commission was appointed, and to this we owe the birth of the many fine research laboratories which have come into existence recently, the work in which has been the subject matter of many most valuable papers and discussions at the Medical Congress recently held at Bombay. But there is, alas, another side to the matter. On the top of the colossal tragedy implied by these millions of deaths we have to remember that in certain districts there was swept away some of the finest recruiting stock for the Indian Army, while the persistence of the epidemic, and particularly the measures which have been taken in some places to arrest its devastations, have led to acute unrest in the native population. On every ground, humanitarian as well as political, we must all hope that the existing promises of permanent abatement will be fulfilled.

The contributors to the proceedings at the Bombay Congress,[1] to which we propose to refer especially, are for the most part experts employed either in research work in Government laboratories or in active plague prevention. The research done has been well carried out by devoted workers in India who have caught the true spirit of scientific research. The newly equipped laboratories which provided facilities for earnest work can, therefore, be intelligently used, and the country is benefiting by the great financial outlay in a corresponding manner. The result of this organised research is now unfolding a new state of affairs as regards plague etiology and prevention. The story is worth recapitulation as a chronicle of advancing knowledge. As is generally known, rats have been associated with plague from time immemorial. The ancient Egyptians figured them in their crude drawings and referred to them in their writings. In modern times the facts that rat mortality preceded outbreaks of plague in man and that there was a disappearance of rats after plague epidemics had worn themselves out were observed, but they were thought to be a coincidence until bacteriological investigation proved that rat mortality was due to the bacillus pestis. The rat was then perceived to be a probable source of the spread of infection and attempts were made to prove it, but not at first with success. Other sources of contagion were examined. Plague patients were said to spread the disease by contact and by their excreta; and it was argued that, as rats die from plague, their excreta, which foul human dwelling places, might aid to infect man; while rats, which will eat their own dead, might keep the infection up. Then, as was inevitable, the work of those who had shown that blood-sucking insects were often the causal agents of the spread of disease, carrying infection from animals to man, and *vice versâ*, attracted the notice of those working on the investigation of plague, and thus the hint was given that plague might possibly be propagated by some form of parasitic blood-sucking insect common to man and rats. In India vermin and parasites of all kinds, especially fleas, are very common; the lower classes of natives and their dwellings are always infested by them, and once attention had been directed to the possibility of some such insect as the flea being the medium of infection the rest followed. It has now been definitely proved that any species of flea common to rat and man is capable of propagating the disease, if it is not also the chief means of so doing. Major **GEORGE LAMB**, I.M.S., member of the Advisory Committee for Plague Investigation, in a paper read before the Bombay Medical Congress, has given a very complete *résumé* of the epidemiology of plague and comes to the following general conclusions, which he considers of the greatest importance from a prophylactic point of view (we quote his own words): "1. Bubonic plague in man is entirely dependent on the disease in the rat. 2. The infection is conveyed from rat to rat, and from rat to man, solely by means of the rat flea. 3. A case of bubonic plague in man is not in itself infectious. 4. Insanitary conditions have no relation to the occurrence of plague, except in so far as they favour infestation by rats. 5. Plague is usually conveyed from place to place by imported rat fleas which are carried by people in their persons or in their baggage. The human agent not infrequently himself escapes infection."

---

[1] A special supplement to the *Indian Medical Gazette* for March contains a good précis of the proceedings of the Congress.

The general subject of the prophylaxis of plague in an infected country was treated at the Congress in a paper by Captain **W. GLEN LISTON**, I.M.S., of the Plague Research Laboratory at Parel. He also pointed out that plague was essentially a rat disease and compared its spread by animals to rabies and glanders. He dwelt on the means and methods best suited for rat extermination and the difficulties of the proceeding owing to the defects in native houses, the general want of a sanitary environment, and the abundance of food—grain and garbage—available for rats in places where natives sleep. Captain **LISTON** advocates the systematic setting of large numbers of rat traps in accordance with a well-organised plan of campaign, for he has noted that where the trapping of rats has failed the cause is due to lack of organisation, defective operations, and want of appreciation of the magnitude of the task by those engaged on the work. Plague is carried by infected rat fleas either on the person, in wearing apparel, bedding, or in merchandise, to rats and human beings elsewhere. Disinfection of all domestic and personal environment is therefore of the utmost importance, and the comparative success of stopping the spread of plague from India over sea must to a great extent be attributed to this precaution. Rat extermination is therefore the first practical step to be taken. A method of rat extermination formed the subject of a valuable communication to the Congress by Lieutenant-Colonel **A. BUCHANAN**, I.M.S. His advocacy of the cat as the most obvious method of destroying rats should appeal to natives of India, especially Hindus, who from their religious doctrines are forbidden to take the life of rats. The cat, if not too well fed, is the natural enemy of the rat and does not become infected with true plague. Professor **SHIGA** of Japan, who was present at the Congress, bore testimony to the efficacy of cats in plague epidemics in the Far East. The importance of preventing the carriage of plague by sea, emphasising the necessity of disinfection of clothing and destroying of rats in the docks of infected seaports, was put forward by Dr. **G. J. BLACKMORE**, who regarded any other attempt to hinder rats getting on board ships in wharf as ineffectual.

The good effects of anti-plague inoculation (by vaccine prepared by the Haffkine method) were ably demonstrated by Major **R. F. STANDAGE**, I.M.S., based on work done in Bangalore in house-to-house inoculation.[2] Amongst a population of 89,599, including the military garrison, 40,573 inoculations were carried out; of these 33 contracted plague, 13 deaths occurring; 13 of the former and nine of the latter may be discounted as the disease occurred within ten days of inoculation, thus leaving 20 attacks with four deaths. Amongst the 49,026 non-inoculated 1653 attacks with 1387 deaths occurred. These figures speak for themselves. Householders popularised the movement by giving "Inoculation At Homes." The debatable question of Recrudescence of Plague was introduced by Major **S. BROWNING SMITH**, I.M.S., who has had charge of the plague preventive measures in the Punjab for many years. In some of his districts plague has recurred after long intervals, during which no signs of infection reaching the area or existing in it were apparent. He attributes the non-prevalence to the fact that the rat population becomes so thinned out or exterminated during an epidemic as to render their power of spreading the emulating Lieutenant-Colonel Keegan's enthusiastic appreciation of extraction of cataract in the capsule. That Major Smith is to be warmly congratulated on his results scarcely requires to be mentioned; that he is doing good service in expounding the advantages which he anticipates from a renewed and invigorated knowledge of an operation which has perhaps been unduly neglected we willingly admit. None the less, great as has been his experience, it must be remembered that it has been acquired in a limited field, and ophthalmic surgeons will be wise in proceeding cautiously before committing themselves to unqualified acceptance of his conclusions in their entirety.

---

[2] Fully described in THE LANCET of June 6th, 1908, p. 1664.

BACTERIAL BAIT.

MICROSCOPIC as bacteria are they have their needs, which in some instances bear an analogy to those exhibited by the human race. It is possible, indeed, to separate certain kinds of bacteria from other kinds by a process of allurement, employing baits for the purpose. Those bacteria, for example, which are concerned in the process of putrefaction may be trapped or separated from the rest by offering them oxygen. A very pretty experiment in this direction consists in employing a thread of a green alga, which under the influence of the sun's rays evolves oxygen, and placing it in a drop of liquid infested with the particular bacteria. The oxygen-loving bacteria will soon gather round the points at which oxygen is evolved, just as so many fishes will be found gathered round a baiting ground. It is clear from this experiment that in the presence of both kinds of organisms, one to whom oxygen is distasteful and the other to whom it is a vital element, a means of separation is afforded. Oxygen, however, is not the only bait which can be used for the purpose of sorting bacteria. Many organisms, for example, are allured by the salts of potassium, while others find asparagin or the sap or juice of raw potatoes irresistible. This method, of course, is the principle of differentiation by which a culture of a definite composition is prepared suited to the needs of a given organism. It applies equally to the pathogenic organism as to the non-pathogenic organism, and has obvious bearings, therefore, upon the interesting but complex problem of the resistance of the human organism to disease.

PLAGUE IN RATS AT A BRITISH PORT.

ENGLAND'S world-wide communications by shipping with foreign countries expose her almost continuously to the risks of importation of exotic infection. To the port medical officer of health and his staff is intrusted the duty in this country of keeping a strict watch against the danger of invasion of our shores by cholera or plague. Occasionally the invader breaks through the first line of defence, but not often. Last year we had to report a small outbreak of plague at the port of Liverpool, comprising three cases on board a barge, but, fortunately, through the exertions of Dr. E. W. Hope, the medical officer of health, the infection was quickly destroyed and no extension took place. And now we have to mention a similar small outbreak, this time among dock rats at the port of Hull. From a printed report recently presented to the port sanitary authority by Dr. J. Wright Mason, the medical officer of health, we learn that some time in February last some dead rats were discovered in a dock shed among sacks of maize which had been landed last October from a steamship coming from a Black Sea port. These rats when found showed no signs of decomposition, and, indeed, had still fleas upon them, a sign that they had not long been dead. They were at once carefully examined in the laboratory by Dr. A. G. P. Thomson, the assistant medical officer of health, and the opinion was formed that these rodents had died from plague. This diagnosis was confirmed by Dr. Klein, to whom specimen rats had been sent. As soon as the provisional diagnosis of plague had been arrived at, Dr. Mason took active steps to ascertain the full extent of the mischief, and for this purpose search was made for dead rats throughout the other sheds in the docks; a large number of living rats were also caught and examined in the laboratory. But neither signs of undue mortality among rodents in any part of the docks, nor any infected animals, could be found. It was evident, therefore, that the infection had been limited to the particular dock shed in which the dead rats had been discovered. Rat-catchers were engaged to trap and destroy all rats in and around this shed, which was then thoroughly cleansed and disinfected. All sacks and articles likely to have been contaminated by the rats were burnt, and all persons who had been employed in the shed were medically examined and kept under supervision for three weeks. These measures and others which were carried out under Dr. Mason's direction, and with the loyal coöperation of the dock company, were entirely successful in suppressing the outbreak. As two months have now elapsed since any plague-infected rats were discovered, and as no trace has been found of infection among any of the large number of living rats which have been caught and examined during that period, it may be safely concluded that the danger is past. We congratulate Dr. Mason upon the success which has followed his well-directed measures, these having apparently freed the port of Hull from a threatened and serious danger

THE ARRANGEMENTS FOR EXCURSIONS AT THE CLOSE OF THE SIXTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

THE detailed arrangements for the Sixteenth International Congress of Medicine have now been issued, with a list of the committees and a programme of the communications accepted by the several sections. The meetings of the Congress will be held in the buildings of the former Polytechnic School, Museum-korut 6/8, and the formal opening will take place in the banqueting hall of the municipal Redoute at 11 A.M. on Sunday, August 29th, 1909. The closing ceremony will occur at the same place on Sept. 4th, at 10 A.M. Six plenary sittings will be held during the Congress, at which addresses will be delivered by Professor Baccelli of Rome, Dr. E. F. Bashford of London, Professor Kütner of Berlin, Dr. Laveran of Paris, and Mr. J. Loëb of Berkeley, U.S.A. A journal will be issued daily and there will be the usual secretarial offices and bureaus. Three new subsections have been formed—viz., orthopædics, professional hygiene, and school hygiene. We described last week the arrangements for lodgings, but the general secretary desires special attention to be called to the difficulty in finding adequate accommodation which intending visitors to Budapest will experience unless they give timely notice to "The Central Travelling Ticket Office iv Vigado-ter 1. Budapest, Hungary," and secure rooms by paying for them in advance. Certain concessions will be allowed by the railway companies to members attending the Congress. In Hungary the railways allow a reduction of 50 per cent. In France the management of the State railways and the East, North, and Orleans Companies also allow a 50 per cent. reduction to members provided with the proper vouchers, whilst in England the Great Eastern Railway grants a reduction to Congress members. Members of the Congress who have paid their subscriptions will receive a circular about the end of May informing them of the method to adopt in claiming these reductions. The executive committee has arranged six excursions for members after the conclusion of the Congress. Each excursion will be "personally conducted" upon the usual inclusive terms, those who pay "first-class prices" will be entitled to a single bedroom in hotels, whilst those who pay "second-class" prices will be lodged in couples. All the excursions will start on Sept. 4th. The first will cost 150 crowns first-class and 135 crowns second-class, a crown being equivalent practically to 1*s.* It includes a visit to Kolozsvar, the ancient capital of Transylvania, the Marosujvár salt mines, and the Rév Pass. Members will return on Sept. 7th. Excursion 2 is to the High Tátra, Dobsina ice cavern, and Pöstyén baths, returning on Sept. 9th. Price 180 crowns first class, 150 crowns second class. Excursion 3 is to Lake Balaton, which is one of the largest and most beautiful pieces of inland water in Europe. Members will return on Sept. 6th. Price 130 crowns first class, 110 crowns second class. Excursion 4. The Lower Danube and Herkulesfürdö, returning Sept. 8th. Price 185 crowns first class and 155 crowns second class. Excursion 5. To Constantinople, returning Sept. 13th. Price 475 crowns first class and 375 crowns second class. This excursion will require passports *visé* at the Turkish and Roumanian consulates. It will allow of five days in Constantinople. The excursionists having visited Constantinople may return *viâ* Trieste by putting into Athens and Corfu, the additional price being 425 crowns. Constantinople will be left on Sept. 11th and Trieste is reached on Sept. 16th. We should presume that this excursion will be modified if no improvement occurs in the political situation in Constantinople before the beginning of September. Excursion 6. To Bosnia, Herzegovina, Dalmatia, and the Hungarian Littoral, returning on Sept. 13th. Price, first class 320 crowns, second class 270 crowns. The latest date of entry for any of the excursions will be August 1st, and in each case a booking fee varying from 25 to 50 crowns, which is not repayable in any circumstances, must be paid. Some of the excursions are necessarily limited in number, so that early application is desirable. So far as can be told at present the Congress appears to be viewed with favour by the medical men of the United Kingdom, for it has secured a larger number of adherents than any International Congress of Medicine since that held in Paris.

THE CLAIMS OF HOME HEALTH RESORTS.

IT is satisfactory to see signs from those who are responsible for the administration of our home health resorts of an increasing zeal to bring before the public the advantages and claims of such places, while at the same time a determined effort is taken to render them more attractive not only in regard to social amusements but in regard also to the attainment of a high standard of sanitary control. Our remarks are prompted by the formation some few years ago at Margate of a chamber of commerce, the objects of which are "to promote, advance, and protect the commercial and general interests of the port and borough; to assist in the development and improvement of the town, and to add to its attractions as an all-the-year-round health resort." This organisation has already borne fruit in favour of the interests of the borough, and it has also served to forward the work of sanitary administration. Margate now possesses a very excellent water-supply derived from the chalk hills lying towards Canterbury, and the disposal of its sewage out to sea is based on methods approved by the highest authorities on sanitary engineering. The air of Margate is, of course, greatly celebrated for its salubrity and wonderful restorative powers. On the occasion of the third annual banquet of this chamber of commerce, which was held on April 26th, the members of the organisation were able again to report progress, a fact which Lord Brassey, Lord Warden of the Cinque Ports, who was present, heartily congratulated them upon. This organisation also causes its lay members to realise the importance and the arduousness of sanitary administration, and they come to watch its application and progress with great interest and to record the results with pride. They also enter into negotiations with the railway companies with the view of inducing them to increase the facilities for enabling the public to reach the place quickly, comfortably, and at reasonable rates. There can be little doubt that as the efficiency of such a scheme of organisation increases so will the patronage of the public increase, and a great portion of it will be weaned from the often erroneous idea that only a foreign health resort can meet their case. We should like, therefore, to see the excellent example of Margate in this matter followed by other health resorts.

THE TREATMENT OF DEEP-SEATED MALIGNANT DISEASE BY THE X RAYS.

THE value of the x rays in superficial carcinomata is well established, but their value in deep-seated malignant disease is doubtful. In the *American Journal of the Medical Sciences* for April Dr. G. F. Pfahler has published an important paper based on the treatment of 35 sarcomata and 304 deep-seated carcinomata. He classes as deep-seated, growths in the subcutaneous, glandular, visceral, and osseous tissues. Most of the cases were recurrent or very advanced and beyond other modes of treatment. His results are encouraging, considering the hopeless character of the cases. In over 50 per cent. of sarcomata he obtained recoveries. The following are some examples. A girl, aged 16 years, had a small round-cell sarcoma of the orbit and was not expected to live a fortnight. She recovered after three months' treatment without damage to the eye. She remained well for four months and then rapid recurrence took place and proved fatal. A man, aged 21 years, had a round-cell sarcoma at the angle of the jaw which grew to the size of an apple in four weeks and was then excised. It recurred and again grew to the same size in four weeks and was again excised. On the fifth day after the second operation it had recurred and was of the size of half a hen's egg. Twenty-two applications of the x rays were made in five weeks and recovery took place. He is now well, three years later. A woman, aged 30 years, was seen in September, 1904. She had a round-cell sarcoma of the frontal, ethmoid, and maxillary sinuses. This was proved by examination of a section of the growth by a pathologist. 416 applications of the x rays were made. The tumour almost disappeared and after two months she returned to her occupation as milliner. She has been quite comfortable for four years. A man, aged 36 years, had recurrence in the wound left after removal of a sarcomatous testicle and a secondary growth in the left groin of the size of a hen's egg. Both growths disappeared in four months after 44 applications. He is still well, six months after the last application. Of the 35 cases of sarcoma the patients are still under treatment in nine and have shown distinct improvement. Of the 26 cases in which the treatment has been discontinued eight of the patients died and 17 recovered or, at least, have been relieved of all symptoms. Of the 17 cases of recovery recurrence took place in two. One of these was fatal and in the other recovery has nearly taken place. Considering that practically all the cases were hopeless the results are remarkable. But Dr. Pfahler does not consider his results an argument against operation. On the contrary, he believes that the best results will be obtained by operation, followed by x ray treatment. With regard to the type of sarcoma the best results were obtained in round-cell sarcoma, then in mixed-cell sarcoma, and then in spindle-cell sarcoma. Three cases of melanotic sarcoma were treated and recovery took place in all. The results in carcinoma were much less encouraging. They are difficult to summarise, as all the patients referred to Dr. Pfahler, some of whom were in a dying state, were treated. Only a few cases of primary carcinoma of the breast were treated and these were inoperable. The results were "as good as those obtained by other methods." In recurrent carcinoma of the breast brilliant results were obtained when the growth was localised. On the other hand, when it was extensive and metastasis had taken place (the majority of cases), only palliation and prolongation of life were, as a rule, obtained. In nearly all cases the tumours underwent some diminution and the patient was made comfortable. In advanced cases remarkable results sometimes were obtained. Thus a woman had two nodules in the scar left after removal of the breast and enlarged supraclavicular glands. After 44 applications in three months she recovered. The glands again enlarged and recovery again took place under the treatment. She is now living five years later. In four cases of carcinoma of the œsophagus improvement was obtained, the power to swallow solid food being restored. In ten cases of advanced carcinoma of the stomach some improved and one patient seemed to recover. In cancer of the rectum good results were obtained from post-operative x ray treatment; life was prolonged for a year or more and the patients were rendered more comfortable. 14 cases of inoperable cancer of the uterus were treated and two of the patients seemed to recover. Pain and discharge were often relieved for a time.

A NEW SEAL OF A ROMAN OCULIST.

IN 1907 the Cabinet des Médailles in Paris, through the generous donation of Commandant Mowat, became possessed of his valuable collection of nine Gallo-Roman oculist seals; this brought up the number of these relics in the Bibliothèque Nationale to 24. Early in 1908 M. Babelon, director of the Département Numismatique, was fortunately able to add another perfectly preserved medical signet, which had been found with a few other small antiquities in the garden of a resident at Langres. The seal is of flat shape, similar to a small dog biscuit, and has its inscription graven upon all four of its edges. It is cut from a piece of pale green steatite and this displays the letters quite clearly. The text is as follows, filling in the abbreviations:—

Lucii Pamii Hygini ad aspritudinem crocodes.
" " " ad omnem lippitudinem.
" " " ad sedatam diasmyrnes.
" " " ad caliginem.

The name of L. Pamius Hyginus is new, not only as far as concerns the cognomena of the old oculists, but also to the large Latin onomasticon. The collyria he employed and the complaints which by their aid he endeavoured to cure are all such as have been found mentioned upon previously known seals, and have been referred to in our columns in recent years. It is worthy of note that the arrangement of the wording is unusual, for instead of, as was commonly done, placing the collyria in each case, first followed by the word "ad," preceding the malady, the order is reversed. In the last line caligo, that is defective, or fading, vision is mentioned but no special curative ingredient given, so for its improvement the oculist appears to have relied upon his general ability. It is not probable that the diasmyrnes, or myrrh, was also intended for the treatment of caligo, because in no other oculist seal, and it is frequently mentioned thereon, is its use suggested for the purpose. In commenting upon this seal, commencing with the collyria, crocodes or saffron was a favourite remedy among the oculists, as in this instance, for "aspritudo," the palpebral granulations of trachoma. Diasmyrnes was the common ingredient for these collyria, and it has been mentioned upon nearly half of the 225 seals hitherto edited. In most cases it is stated to be useful for the cure of "lippitudo," or suppurative conjunctivitis. Here, however, the mention of the disease is qualified by the word "sedatam," indicating that its virulence was abating when Hyginus deemed the application of myrrh would prove beneficial. This qualifying term has only twice before appeared upon these seals. Upon one the text reads, "ad sedatas lippitudines," whilst upon the other "ad sedat(iones)" occurs. These oculists' seals are relics of which it is quite easy to make plaster-cast replicas, and it would be interesting if the museums of different countries would exchange casts of the respective seals in their keeping.

A PHYSIOLOGIST AS ARTIST.

Dr. Leonard Hill, who besides being an accomplished physiologist is a representative of the Faculty of Medicine of the University of London on the Senate of that body, finds time among his multifarious occupations to paint pictures, an exhibition of which is now being held at the Corner Gallery, 49, Old Bond-street, W. From a leaflet which is inserted in the catalogue we learn that, "In painting he paints to please himself, and delights in trying to catch some feeling of the light, atmosphere, and colour of landscape, and the expression of the animals he keeps at his house at Loughton." The pictures are deliberately rough, but they succeed in the points to which attention is thus drawn. For instance, Nos. 17 and 18, "The Tree Clump by the Sea" and "Autumnal Evening," well express a cool misty atmosphere, while No. 7, entitled "Vanquished," depicting a depressed-looking cock, should stimulate the artist to give his unhappy subject a dose of oxygen, make him try again, and then paint another picture and call it "Victor." The little exhibition shows Dr. Hill's versatility and artistic accomplishment in a marked manner.

FATAL ELECTRIC SHOCK IN TURNING ON THE ELECTRIC LIGHT.

IN the *Boston Medical and Surgical Journal* of Feb 25th Dr. F. E. Jones has reported the following case. A strong man, aged 21 years, worked at a forge in a machine shop. Over the forge hung a 16 candle-power incandescent electric lamp. He reached for the lamp apparently to turn on the light and cried out. His fellow workmen rushed to him and found him rigid, leaning against an adjacent wooden partition, and tightly clutching the lamp with his right hand. On breaking the contact with the lamp he fell to the floor. Efforts to resuscitate him by artificial respiration failed. All the middle joints on the back of the right hand were burned and the bone was laid bare. The lamp was hung on cords from the rafters, where its wires tapped the main wires of the building, which carried 110 volts of electricity. Careful examination failed to reveal anything out of order in the electric supply of the building; the fuses were in place at the entrance of the wires and in each lamp. In the vicinity of the building were wires carrying a much higher voltage (2300 volts) from the generating station to transformers, which reduced the voltage in the secondary currents supplied to the houses to 110. The wires from the building led to a transformer several hundred yards distant. A current of 110 volts is ordinarily used for electric lights and is quite safe to handle; it may pass through the body without causing anything alarming. The fatal shock must have resulted in some way from the primary current of 2300 volts escaping to the wires of the lamp. An electrical expert explained the accident as follows. By various means, for example, by the limbs of trees rubbing against the wire of the primary current, an opportunity may be given for escape to earth. This, however, may not occur unless a second mode of escape is possible. Then a short circuit is formed through earth from one point of escape to the other, as it offers the least resistance to the current. In this case probably one leak occurred somewhere in the primary circuit as a result of a tree rubbing against the wire. The current was then, so to speak, waiting for another leak to earth. The coils in the transformer, in consequence of poor insulation or other cause, may have allowed the primary current to escape on to the secondary wire. When the man seized the lamp he formed the second connexion with earth and the primary current of 2300 volts passed through him. In THE LANCET of Jan. 26th, 1907, p. 246, we referred to a similar accident which also occurred in America. A man received a fatal shock while using the telephone and holding an electric lamp. This was attributed to the main electric and telephone wires having been swayed together by the wind where they crossed, the insulation being burnt off, and a current of 3500 volts passing into the telephone wire. In the system of electric lighting now installed in Boston a device is adopted to prevent such accidents. The secondary wire is connected with earth at the transformer. If any of the primary current escapes to the secondary wire it therefore at once goes to earth.

RAILWAY HYGIENE.

"THE exceptionally severe incidence of influenza among the travelling public in Italy," writes an Italian correspondent, "has prompted Dr. Carlo Giongo, the well-known 'chimico igienista' (sanitary chemist) to inquire into its causes, and one of these he finds in the conditions worse than 'untidy,' nay, positively filthy, in which the said public are conveyed over the railway lines. It is no disparagement of Dr. Giongo's conclusions to state that these had been anticipated nearly half a century ago by THE LANCET'S Special Commission[1] on the sanitary risks attending railway travel in the British Isles—a Commission whose authority so impressed the travelling world that the railway companies lost no time in acting on the suggestions indicated, and, in quite a proper spirit, consulting the interests of the passenger coincidently with their own. The result has been that with few, if any, exceptions the British lines maintain an honourable lead over their Continental sisters in all that pertains to the observance of hygienic law and social amenity—a lead which, the *Gazzetta del Popolo* of Turin remarks, is best appreciated by a comparison of the Italian railways with those of the conterminous states and of these in turn with those of the British Isles. It is customary in Italy, continues the Subalpine journal, to bewail the 'disservizio' (perfunctory service) of her railways, but the evils denounced by Dr. Giongo are quite other than those connected with the time-table. Nay, they are quite as real, though not so gruesomely impressive, as those of the all too frequent 'derailments' or 'collisions' occasioned by an undermanned, underpaid, and overworked *personnel*. That '*ensemble* of "sudiceria volgare" (common filth) which seems to cling to the railway carriages of all three classes,' says Dr. Giongo, 'forms a kind of El Dorado for countless bacilli, which enjoy a "free pass" over all the Italian lines from the Alps to Etna.' Among those bacilli he places first that of influenza—that of tuberculosis coming next as 'a good second.' Having illustrated this by bacteriological considerations, he proceeds in his monograph (published in the principal weekly journal of Italy, the *Marzocco* of Florence) to insist on the appropriate remedy, which is shortly this—a thorough systematic cleansing process applied on a scale and with a vigilance long practised in the British Isles, coupled with apparatus for arresting the diffusion of dust and for disinfecting every compartment on the arrival of each train at its terminus. Descending to details, he urges the frequent change and 'sterilisation' of the cushions, particularly where the head is apt to recline. This recommendation he might have reinforced by citing the remarks made in its support by THE LANCET Commission, prominent among them being the rise of temperature in heated carriages the windows of which (too frequently in continental experience) are hermetically sealed, and the consequent liberation from the cushions or woollen paddings of effluvia absorbed from successive relays of passengers with whom personal ablution or abstersion is not a persistent habit! Dr. Giongo's appeal to the State (which in Italy is now vested with control of the railways) ought to be driven home by the Association for Promoting the Influx of Visitors into Italy—an 'association' which includes (besides members of both Houses of Parliament) many representatives of the banking, industrial, and hotel-keeping interests, and which might appropriately follow up the reforms it has already wrought in the houses of entertainment, urban and provincial, by measures for safeguarding the health of the traveller, seriously endangered as that has lately been by the insanitary conditions prevalent on the main Italian lines."

A TELEGRAM from the Governor of Hong-Kong to the Secretary of State for the Colonies states that five cases of plague were reported during the week ending April 24th, the number of deaths being three. Another telegram received at the Colonial Office from the Governor of Mauritius states that three cases of plague were reported during the week ending April 22nd, the number of deaths being three.

A SPECIAL meeting of the Dermatological Section of the Royal Society of Medicine will be held at 20, Hanover-square, London, W., on May 20th, at 5 P.M., when Dr. Louis Wickham of the Radium Institute, Paris, will give a lecture-demonstration on the Therapeutics of Radium.

THE CHARITABLE DISPENSARIES IN THE PUNJAB.[1]

BY D. F. KEEGAN, F.R.C.S. ENG.,

BRIGADE SURGEON LIEUTENANT COLONEL, I.M.S. (RETIRED).

MAY I be allowed to direct attention to Colonel Bate's report on the working of the charitable dispensaries in the Punjab in connexion with the annotation entitled "The Medical Factor in our Tenure of India"[2]? This report presents some features of great interest and deserves more than a passing notice. The aspiring specialist in ophthalmic and genito-urinary surgery in the British Isles who dips into its pages will with difficulty suppress a feeling of envy tinctured by sadness that his opportunities for rapidly acquiring manual proficiency in his own special sphere of surgery are so meagre in comparison with those of most civil surgeons whose lot is cast in the Punjab. For this report deals with 23,270 extractions of cataract, 3583 operations for artificial pupil, and 6782 operations for stone in the bladder. Irrespective, however, of the surgical interest of the report, there is a still larger and broader interest attached to it by reason of its review by the Lieutenant-Governor of the Punjab, Sir Louis Dane.

Directing our attention in the first instance to the operations for stone in the bladder, we find that out of a total of 6782 operations as many as 6034 were treated by the crushing method, with a mortality of only 2·62 per cent. To this percentage we must, however, add 1·2 per cent. for cases which appear in the columns of the report as "discharged" and "relieved" and therefore the percentage of unsuccessful results following on 6034 crushing operations amounted to

---

[1] THE LANCET, January and February, 1862.

[1] [illegible] Dispensaries [illegible] E. L. Bate, [illegible]

3·82. Half, or somewhat more than half, of these 6034 crushing operations were performed on very young boys and youths, and the remainder on males varying from 16 or 18 years of age to men of very advanced years. In many cases, both in early life and advanced age, the stones dealt with were of very considerable size. These results must be considered by all competent judges as being eminently satisfactory, and are conclusive evidence that there are many past-masters in the craft of crushing vesical calculi in the Punjab. Turning to the cutting operations, which embrace suprapubic, lateral perineal, median and vaginal lithotomies, we find that the death-rate following 683 operations amounted to 11·7 per cent., excluding unsuccessful cases appearing under the headings "discharged" and "relieved." The lateral perineal lithotomies amounted to 499 cases with 55 deaths—a mortality of 11·02 per cent.; and if the "discharged" and "relieved" cases are included, the percentage of unsuccessful results amounted to 14·22. The suprapubic lithotomies amounted to 130 cases with 21 deaths, a rate of mortality of 16·15, and if the "discharged" and "relieved" cases are included the unsuccessful results amounted to as much as 25·38 per cent. If the great majority of these 130 suprapubic lithotomies were undertaken for the cure of very large calculi then the results must be considered as satisfactory; but if they were undertaken for small calculi, and the report throws no light on this point, then the results must be considered as very unfavourable. In pleasing contrast with the results following the 130 suprapubic lithotomies, 50 perineal litholapaxies were performed with four deaths, a mortality of only 8 per cent. Perineal litholapaxy is only performed in the Punjab when the stone is so large or so hard that it cannot be dealt with by Bigelow's method of urethral litholapaxy. The results which followed these 50 perineal litholapaxies go to prove what most surgeons in India who have had a large experience in treating vesical calculi have for some years believed—viz., that perineal litholapaxy or perineal lithotrity is a far better operation for very large vesical calculi than suprapubic lithotomy. Dealing with the grand total of 6782 operations for vesical calculi, we find that the proportion of crushing to cutting operations was as 8·8 to 1, and the proportion of failures following the crushing method was as 3·82 to 15·92 after the cutting methods. Or in other words, litholapaxy was more than four times as successful as lithotomy. Some years ago, when the great success achieved by surgeons in India in performing litholapaxy had begun to attract the attention of the profession in England, it was conjectured that this success was due to the great tolerance of the Indian bladder to the manipulations of the lithotrite. I need hardly point out that the statistics just quoted completely dispel this cherished illusion of the unskilled lithotritist in this country. No. Litholapaxy has triumphed in India simply because surgeons practising in our great dependency enjoy unrivalled opportunities of rendering themselves practically familiar with the lithotrite and have learned by experience how to use it with precision and dexterity.

Coming to the cataract operations, they amounted, as already stated, to the large total of 23,270, and the percentage of good vision obtained was 93·42. This percentage of success may be considered fairly satisfactory when we bear in mind that the operations were performed by a number of surgeons of varying degrees of skill and experience in cataract extraction. In Jullundur, however, where Major Henry Smith, I.M.S., performs extraction in the capsule, the success obtained was over 99 per cent. Out of the total 23,270 Major Smith must have performed about 8000 operations, for in the year 1906 he did as many as 2974 extractions, and therefore the percentage of success obtained by the average operator in the Punjab fell considerably below 93·42. Extraction in the capsule has been practised in India for several years. Lieutenant-Colonel T. R. Mulroney, I.M.S., and his assistant, the late Rai Bahadur Mehr Chand, practised it systematically. For the last 15 years Lieutenant-Colonel G. H. D. Gimlette, I.M.S., has also performed it as a routine operation. But to Major Smith of Jullundur the great credit is due of developing the technique of the operation to a surprising pitch of excellence, and as readers of THE LANCET are aware his experience of cataract extractions now extends to 20,000 cases.[3] This, perhaps, is not the time to discuss the relative advantages of extracting cataracts in the capsule as compared with the method generally adopted when the capsule is incised. Ophthalmic surgeons in Great Britain and throughout Europe look askance at extraction in the capsule, and the three leading professors of ophthalmic surgery in India have steadily opposed it. But members of the Indian Medical Service, in charge of large civil medical institutions, have never been much influenced by professional dicta. They are very independent and go their own way when once they feel that they are on the right track. There is no getting away from the fact that extracting cataract in the capsule is the ideal operation if a surgeon can do it well. It is the operation which has been the dream of all enthusiastic ophthalmic surgeons the world over, but a dream so seldom realised. It has, however, been reserved for India to realise this dream, and the brilliant results which Major Smith has achieved for some years at Jullundur have stimulated some of the more progressive and junior members of the Indian Medical Service to repair to Jullundur and there to learn the technique of the operation under Major Smith's personal supervision, and there can be little doubt that in a few years the number of surgeons in the Indian Medical Service who will perform extraction in the capsule as the operation of election will rapidly increase. For immature cataracts, extraction in the capsule is the operation *par excellence*, and when well performed the after-treatment is extremely simple and satisfactory, and secondary operations are never required. When extraction in the capsule becomes a popular operation among ophthalmic surgeons in India a great boon will be conferred on natives of the country who are now obliged to waste long periods of time whilst waiting for their cataracts to ripen.

And now to pass from the strictly professional aspects of the report to subjects of administration. The Inspector-General of Civil Hospitals having drawn attention to the inadequate number of dispensaries in certain districts, the Lieutenant-Governor remarks :—

> It has, however, to be remembered that local bodies will probably never be able to provide medical assistance at every man's door, and the time has now come when, having set an example, Government and the local authorities may expect unofficial doctors to step in and fill up the gaps. They will at first need protection against the charitable competition of the public dispensaries, to which even the well-to-do resort unfairly for gratuitous medical relief, and still more a sympathetic backing from Government officials as a support to their prestige and reputation; but, given this assistance, there can be little doubt that the future extension of medical practice in rural tracts must be largely in the hands of the private practitioner.

These remarks are most important as heralding a wider sphere of activity for native medical practitioners educated at the expense of Government, and it is to be hoped that they may take them to heart and start practice on their own account, and so oust the native quacks who prey on the unsophisticated villager. It will be observed that the well-to-do native of India does not fall far behind his well-to-do brother in the West in approaching the out-patient department of hospitals *in formâ pauperis !*

Regarding the system of financing the medical institutions in the Punjab the Lieutenant-Governor's remarks are very weighty :—

> There are few charitable objects upon which money can be more profitably expended than the dispensaries, and the Lieutenant-Governor hopes that the Indian public will gradually come to realise this. Now that arrangements have been made for enabling subscribers to earmark their subscriptions for particular objects and particular dispensaries, each subscriber will be able to see for himself the good he is doing to his fellow men, and it may be that the personal pride in an institution which he has helped to develop will open the purse-strings of many who have hesitated to give what has hitherto been really a mere donation to the funds of the district board, a body to which no particular sentiment can attach. It is by private subscription that the better classes who use the dispensaries can show their gratitude for the benefits received. With regard to public funds, the Lieutenant-Governor has in a recent case expressed the opinion that a larger share of the financial resources of the province should in future be devoted to medical relief even, if necessary, at the expense of checking somewhat the rate of the progressive expenditure on higher education. If increased expenditure on any department is feasible, the medical department has the first claim.

Here we find enunciated by a Lieutenant-Governor for the first time, as far as I know, the wholesome doctrine that "immediate care of the body," charity, in fine, should take precedence of "higher education" in India. Writing about the dearth of small lithotrites in district dispensaries in India some nine years ago in the special Stone Number of the *Indian Medical Gazette* I remarked : "In the Punjab, Sind, the North-West Provinces, and in some districts of the Bombay Presidency where stone in the bladder is prevalent, the peasant in the fields has a right to look to Government that his son, when suffering from stone in the bladder, should have it extracted by a crushing and not by a cutting operation. It may be argued that the expense of furnishing branch dispensaries with complete sets of litholapaxy instruments would be a very heavy one. Doubtless it would be, but local governments could easily divert a small portion of their educational funds for such a charitable purpose. It is the peasant who pays all our salaries in India, and our pensions when we retire, and surely he has the first claim on our charity, and it seems hard that he should be obliged to toil in order that the rich *bunniah's* son may receive an educa[illegible] expense."

---

[3] THE LANCET, August 15th, 1908, p. 452.

[illegible] ngress decided [illegible]," is to be the watchword which should guide future Christianising efforts in India. The Government of India might well adopt the same motto and apply it to their own medical service in these days of unrest in their great dependency. There can be no clashing of interests between the Indian Medical Service and the Association of Medical Missionaries, for charity in its widest acceptation is the bed-rock principle of both. Members of the Indian Medical Service know full well what noble work the Medical Missionary Association, which now numbers more than 300 fully qualified medical practitioners of both sexes, has done for many years in India, and how much this charitable work has tended towards inducing the native to view the Great Sirkar with a more and more trustful and kindly eye. And the association has done this by the proficiency of its members in medicine and more especially in operative surgery. One member of the association living in a station on the bank of the Indus has done nearly a thousand operations for stone in the bladder during the last 15 years, and the aggregate number of important surgical operations performed in one year by the combined members of the association throughout the length and breadth of India is immense.

There are many ways of strengthening and reinforcing the Indian Medical Service even without adding to its numbers, which would, of course, entail a heavy expenditure of money in salaries and pensions. For instance, civil hospitals and dispensaries throughout India should be furnished with operating-rooms fully equipped in every particular to carry out aseptic surgery. To do this the sinews of war must be found, for modern surgery costs money. We have in India for some years lagged behind our surgical brethren in England and in Europe generally in the wide field of abdominal surgery through lack of suitably equipped operating-rooms. When these are supplied throughout India, Indian medical officers will be able to show as good results in abdominal surgery as they have done in the past in operations for cataract and stone in the bladder. The Inspector-General of Civil Hospitals, United Provinces, in his triennial report for the year ending 1907 writes *apropos* to an increase in the number of surgical operations:—

> [illegible]'s due in large [illegible] ple and to the [illegible] lern surgical [illegible] to operative [illegible] rgical equip- [illegible] onel Joubert, commenced a campaign against obsolete instruments and obsolete methods which is now beginning to bear fruit, and I have done my best to continue the good work by building new operating-rooms and removing defects from old ones wherever it has been possible. There is hardly an operating-room in these Provinces which has not been either rebuilt or remodelled during the past three years or for which structural alterations have not been proposed. My work in [illegible] assistant surgeons now undertake formidable abdominal and other operations with success which formerly were precluded on account of the dirty surroundings under which they had to be performed.

Better late than never. But it seems strange that the medical institutions in the United Provinces should have been obliged to wait so many years for adequately equipped operating rooms to carry out modern surgery which confers a priceless boon on the poor peasant, while large sums of money were being spent on "higher education," which can only benefit the well-to-do.

For centuries in India the itinerant coucher of lenses has been permitted to play havoc on the eyes of the simple villager afflicted with cataract, and the amount of irretrievable blindness which follows in the wake of these surgical quacks is immense. There are many members of the Indian Medical Service besides civil surgeons who are specialists in ophthalmology. If at certain seasons of the year these officers were deputed to travel through the country districts surrounding their military stations, and were supplied with tents and competent hospital assistants, ophthalmic surgery would be brought to the villages and the native coucher's occupation would be gone. The busy and hard-worked civil surgeon in the periodical inspections of his district branch dispensaries has not the time to carry out cataract operations efficiently, for he cannot do what the coucher does. He cannot decamp to a neighbouring village an hour or two after operating. He must look to the after-treatment of his cases, but there is not time to do this, and consequently the villager afflicted with cataract must come to the headquarters of the civil surgeon when he wants relief. But all who know India well are aware that though many villagers will travel hundreds of miles on foot to seek the skill of a renowned ophthalmic surgeon, many more are content to await the advent of the coucher and to trust to kismet.

In these days of unrest in India the native whom we should endeavour to influence and conciliate is the man in the field, not the voluble man in the street who wears patent-leather boots and is veneered with English. We want to influence for good the millions of patient, silent, hard-working villagers, the backbone of the country. Such men care little for Legislative Councils and Electoral Colleges. What they require is relief from suffering and bodily ailments and a just and sympathetic rule; and as long as we have them on our side we need not fear the future. The members of the Medical Missionary Association and the Indian Medical Service are potent instruments of conciliation between the governing Briton and the subject races in our great dependency; and no strangers in India know the native more intimately than they do, for it is their lot to watch and tend him when stricken by disease or accident. And it is then that his many fine qualities are best seen and recognised. And the doctors are amply rewarded by the gratitude and implicit trust reposed in them by the native. All this being so, one is tempted to ask, Was it expedient to issue within recent years rules and regulations regarding the acceptance of fees which have wounded the *amour propre* of a great medical service?

SANITATION IN INDIA.

III.[1]

Eastern Bengal and Assam.

THE annual sanitary report of the Province of Eastern Bengal and Assam for 1907 is furnished by Lieutenant-Colonel E. C. Hare, I.M.S., the Sanitary Commissioner of this province. We find that there was a marked absence of high floods and that the rainfall was practically deficient throughout the province in 1907, in contradistinction to the heavy floods that occurred in 1906. The provincial birth-rate was 37·01; this was lower than either the rate for 1906 (37·38) or the rate of the previous five years (39·31). The death-rate was 29·30, which was also lower than that for 1906 (31·67) and that of the last five years (32·19). The decrease in the mortality ratio amongst infants seems chiefly to have benefited those under one year of age. Males gave a greater mortality (30·23) than females (28·34), excepting young adult females, in whom the mortality was higher than among males. Lastly, as regards the mortality, the fall chiefly affected "other classes," the Hindus, and the Mohammadans only showing a slight decrease, whilst amongst the Buddhists there was a slight increase.

Respecting the chief diseases, the mortality from cholera gave a provincial death-rate equalling the mean of the past ten years (2·58), but the districts of Rajshahi, Bakarganj, and Noakhali suffered severely; the last two districts have the disease always more or less prevalent, as owing to their position in many parts it is extremely difficult to get water fit to drink. With respect to small-pox, the provincial mortality (0·29) was somewhat higher than that and of medical men who work for them in localities where policies for comparatively small amounts are taken out. On the one side, it may be pointed out to the companies that a thorough and careful examination, such as should be made where important pecuniary interests are involved, is not adequately rewarded by a fee of half a guinea, and that although they are entitled to expect a medical man to carry out what he undertakes, as a matter of business it cannot be to their interests to underpay him. On the other hand, a medical man should remember that a document to which he appends his signature is a statement to which that signature attests his full and unreserved assent. If he signs a document which declares that he has "this day carefully examined the proposed person," when in fact he has not done so, he places on record a statement which is untrue and for which he may at any time be made answerable. The fact that the fee which he is to be paid is not an adequate one is no excuse in such circumstances, though such a fee may be, and, in the interest of the medical profession, should be, refused.

---

[1] Nos. I. and II. were published in THE LANCET of April 10th (p. 1067) and 24th, 1909 (p. 1199), respectively.

Liability for Medical Fees.

A case of some interest to medical men as to their right to recover their fees from third parties came recently before the county court at Newport in the Isle of Wight. Mrs. Woodhall, of Roland-gardens, South Kensington, described as a lady of considerable means, was sued by a medical man for £37 for attendance on the defendant's sister. Whilst staying at Yarmouth, Isle of Wight, in September last, the defendant's sister (Miss Langton) was thrown out of a motor-car and sustained a broken leg. A medical man attended the lady, paying over 50 visits. From time to time defendant was consulted about the case. When the plaintiff sent in his bill the claim was repudiated. On behalf of the plaintiff it was argued that the defendant not only approved Roentgen ray treatment when it was recommended by the plaintiff, but paid for it. Counsel for the defendant suggested that the host of the young lady should pay, but his honour held that that was a very strong proposition. If hosts were to be held responsible in such circumstances it would do much to upset week-end visits, now so much in vogue. His honour gave judgment for the full amount claimed, with costs, holding that defendant had held herself out as responsible for the payment for her sister's medical attendance. Medicines and medical aid are necessaries for which an infant may contract and render himself liable, but a parent is not liable to pay for such necessaries furnished to an infant child without some proof of a contract on his part, either express or implied, and no such contract will be implied where the infant has been allowed a sufficiently reasonable sum for his expenses (Crantz *v.* Gill, 4 Esp. 471). Where a father of a family had several of his children living at a distance from his own house, under the protection of servants, it was held that if an accident happened to one of the children he was liable to pay for the medical attendance on such child, although he might not know the surgeon called in, and although the accident might have arisen from the carelessness of the servant (Cooper *v.* Phillips, 4 C. & P. 581). In dealings between medical men and the guardians of an infant it must be borne in mind that although the expenses of an extraordinary illness do not form part of the maintenance of an infant strictly speaking, yet where there has been no extraordinary illness physic and doctors' fees must be included in the general allowance for past maintenance, and the court will not allow the guardians to claim an extra sum for the same. A master is not bound to provide medical assistance for his servant, but the obligation (if any) must arise from contract; nor will such a contract be implied simply because the servant is living under the master's roof. In all cases where a servant falls ill and is unable to pay for medical assistance, the parish is bound to supply such assistance, although the servant may not have, previously to his illness, received or stood in need of parish relief (Newby *v.* Wiltshire, 2 Esp. 739). Where a servant, who hurt her foot in getting over a gate, called in a surgeon who was not the regular medical attendant of the family without being desired to do so by her master or mistress, it was held that her master was not liable to pay the surgeon's bill (Cooper *v.* Phillips, 4 C. & P. 581). A master is bound to provide an apprentice with proper medicines and medical attendance (R. *v.* Smith, 8 C. & P. 153). While a husband and wife are living together it is a presumption of fact that the wife is agent for, and has the authority of, her husband to pledge his credit for goods supplied to their establishment which are suited to her station. A wife has implied authority to bind her husband for reasonable expenses for medicines and medical attendances incurred during illness, but this implied authority is put an end to if the husband has given sufficient notice that he will no longer be responsible for any debts which she may incur. A medical man can recover professional charges according to a scale varying with the class of patients visited, provided that the same be fair and reasonable. In all professional dealings between medical men and their patients the customs of the profession will be considered as imported into the contract unless excluded expressly or by implication.

Prosecutions under the Factory and Workshop Act, 1901, in the City.

At the Guildhall recently summonses were heard by Alderman Sir Henry Knight against Messrs. Laurence and Co., blouse manufacturers in the City, for having employed four young persons under the age of 16 years for more than seven days without having obtained certificates in the prescribed form of their fitness for their employment. As a matter of fact, two of the girls had been employed for three months and the others for four and 11 months respectively without being examined by the certifying surgeon, so that the offence was hardly to be described as a technical one only, in spite of the fact that since attention had been called to the matter they had been examined and had been granted certificates. Sir Henry Knight, however, seems to have thought otherwise, for he is reported as having said that the matter was not very important and he inflicted a fine of 1s. only in each case, with costs. The following dialogue at the conclusion of the hearing is taken from the report in the *Daily Telegraph*:—

> Sir H. Knight: What are the costs? I really cannot hear these ladies, they will not speak up. That one (indicating Miss A. M. Newton, the inspector of factories who appeared in support of the summonses), has been better since I cautioned her. (Laughter.) The Chief Clerk: The actual out-of-pocket expenses are 27s. Sir H. Knight: I shall not give her a half-penny more. (Laughter.) This is one of those harassing Acts of Parliament which are driving business out of the City altogether. Still that is no reason why these people should not do what the law requires.

It is to be regretted that such an expression of opinion should have been uttered by a magistrate in enforcing a section the effect of which is to prevent young persons—i.e., children under 16 years of age—from being employed at work for which they are physically unfit. The Act of Parliament to which he referred as driving business out of the City applies to the whole of the United Kingdom. The attitude adopted by the learned alderman towards the women factory inspectors who, in the course of their official duties, conduct prosecutions, may point to the desirability of employing solicitors or barristers to appear in court, but no doubt it is not thought desirable to incur unnecessary expense where the law and facts are not in dispute.

Looking Back.

FROM

THE LANCET, *SATURDAY*, April 30th, 1831.

CHRONIC BRONCHITIS—PARAGORIC ELIXIR.[1]

From William's Ward a case of chronic bronchitis was presented, which had existed many years. There was sonorous and sibilous rattle in various parts of the chest, and copious frothy expectoration, with cough and dyspnœa. There was from time to time a great increase of the difficulty of breathing,—spasmodic dyspnœa. He was relieved, he said, very much by taking the compound tincture of aloes saturated with bruised aniseed. There is a sort of elixir, a secret medicine, which evidently contains a great deal of aniseed, and certainly in many cases of spasmodic difficulty of breathing, affords very great relief. I endeavoured to imitate it at the suggestion of Dr. Prout, who found in it myrrh and aloes, and considered it in every respect a compound tincture of aloes, only that it is made with rum instead of spirits of wine, and an abundance of aniseed. Of this he took one or two drachms three times a day, and, he said, with great relief. I know that many persons regret that the London College have altered paragoric. Paragoric elixir formerly contained a quantity of aniseed, and old practitioners who have used the old for many years, have told me frequently, that it is more effectual in relieving cough than paragoric as it is now made. I believe it was omitted on account of aniseed being supposed to possess no particular virtue, and yet being nauseous to many people. One gentleman told me that an old physician was very cross on hearing him regret that the aniseed was omitted, and declared that it was very properly omitted, for it turned everybody's stomach. But those best acquainted with paragoric believe, that though it may turn the stomach, the old medicine answered better. I can hardly say that I have, myself, made sufficient observations upon the two, but I have heard some elderly practitioners say, that there is a great difference in the effect of the two, and that they now keep two kinds, the new for the prescriptions of others, and the old for those who are wholly under their own care.

---

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 9203 births and 4983 deaths were registered during the week ending April 24th. The annual rate of mortality in these towns, which had been 17·0 and 17·1 per 1000 in the two preceding weeks, declined to 15·8 per 1000 in the week under notice. During the first three weeks of the current quarter the death-rate averaged 16·6 per 1000, while in London during the same period the mean rate was 16·1. The lowest recorded annual death-rates in these towns last week were 7·1 in Hornsey, 7·5 in Reading, 7·7 in Ipswich, and 8·5 in Willesden; the rates in the other towns ranged upwards to 21·1 in Preston, 21·4 in Plymouth, 22·4 in Wigan, 24·3 in Middlesbrough, and 26·5 in Swansea. In London the recorded death-rate during the week was 15·0 per 1000. The 4983 deaths from all causes in the 76 towns last week showed a decrease of 414 from the number in the preceding week, and included 518 which were referred to the principal epidemic diseases, against 593 and 584 in the two preceding weeks; of these 518 deaths, 265 resulted from measles, 131 from whooping-cough, 48 from diphtheria, 33 from diarrhœa, 28 from scarlet fever, and 13 from "fever" (principally enteric), but not any from small-pox. The 518 deaths from these epidemic diseases in the week under notice were equal to an annual rate of 1·6 per 1000, against 1·9 in each of the two preceding weeks; in London also the recorded death-rate from these diseases last week was equal to 1·6 per 1000. No death from any of these epidemic diseases was registered last week in Cardiff, Newport (Mon.), Hastings, Wallasey, or in six other smaller towns; the annual death-rates therefrom ranged upwards, however, to 3·5 in East Ham, in Wolverhampton, and in Stockport, 3·7 in Swansea, 5·8 in Wigan, and 7·1 in St. Helens. The fatal cases of measles in the 76 towns, which had declined from 438 to 321 in the five preceding weeks, further fell last week to 265; the highest death-rates from this disease were 2·4 in Derby, 2·5 in Devonport and in Wolverhampton, 2·9 in Plymouth, 3·8 in St. Helens, and 4·0 in Wigan. The deaths from whooping-cough, which had been 103, 107, and 130 in the three preceding weeks, were 131 in the week under notice, and caused death-rates ranging upwards to 1·2 in Wigan, 1·8 in Preston, 2·7 in St. Helens, and 3·2 in Swansea. The fatal cases of diphtheria, which had bee
rose to 48 last week,
being 1·3 in West H
and the 13 referred to "fever" showed a decline in each case from recent weekly numbers, and the 28 fatal cases of scarlet fever were fewer than the number recorded in any previous week of this year; 10 of the scarlet fever deaths belonged to London and its suburban districts, four to Liverpool, four to Manchester, and two to Sheffield. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had decreased from 2873 to 2294 at the end of the seven preceding weeks, had further declined to 2219 on Saturday last, April 24th; 265 new cases were admitted during the week, against 273, 256, and 244 in the three preceding weeks. The registered deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 310 and 341 in the two preceding weeks, declined again to 294 in the week under notice, and were 18 below the corrected average number in the corresponding week of the five years 1904–08. The deaths in London directly attributed to influenza numbered 45 last week, and were 20 above the corrected average number. The causes of 43, or 0·9 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in London, Manchester, Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, and in 50 other smaller towns; the 43 uncertified deaths included six in Liverpool, six in Sheffield, five in Birmingham, and three each in Bury, Blackburn, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 17·7 and 18·4 per 1000 in the two preceding weeks, declined again to 17·4 per 1000 in the week ending April 24th. During the first three weeks of the current quarter the annual death-rate in these towns has averaged 17·8 per 1000, and exceeded by 1·2 per 1000 the rate during the same period in the 76 large English towns. Among the eight Scotch towns the death-rates in the week under notice ranged from 14·0 in Leith and 14·1 in Aberdeen to 18·5 in Edinburgh and 21·0 in Paisley. The 620 deaths from all causes registered in the eight towns last week showed a decline of 36 from the number in the previous week, and included 86 which were referred to the principal epidemic diseases, against 90 and 98 in the two preceding weeks; of these 86 deaths, 46 resulted from whooping-cough, 18 from diarrhœa, eight from "fever," six from measles, five from diphtheria, and three from scarlet fever, but not any from small-pox. These 86 deaths from epidemic diseases were equal to an annual rate of 2·4 per 1000, or 0·8 more than the mean rate during the week under notice from the same diseases in the 76 English towns. The fatal cases of whooping-cough, which had been 47, 55, and 58 in the three preceding weeks, declined again last week to 46, of which 22 occurred in Glasgow, nine in Edinburgh, seven in Aberdeen, three in Dundee, three in Greenock, and two in Paisley. The 18 deaths from diarrhœa corresponded with the number in the preceding week, and included six in Glasgow, four in Dundee, three in Edinburgh, two in Aberdeen, and two in Leith. The deaths referred to "fever," which had been seven and four in the two preceding weeks, rose again to eight in the week under notice; these eight deaths included four from enteric fever in Glasgow and one in Leith, and one from cerebro-spinal meningitis in Edinburgh, one in Aberdeen, and one in Perth. The six fatal cases of measles exceeded the numbers in other recent weeks, and included five in Paisley. Three of the five deaths from diphtheria, and two of the three deaths from scarlet fever were registered in Glasgow. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 108 and 135 in the two preceding weeks, declined again to 118 in the week under notice, but exceeded by five the number returned in the corresponding week of last year. The causes of 13, or 2·1 per cent., of the deaths registered in the eight towns last week were not certified; in the 76 English towns the proportion of uncertified causes of death during the same week did not exceed 0·9 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been 25·5 and 27·7 per 1000 in the two preceding weeks, declined again to 24·5 per 1000 in the week ending April 24th. During the first three weeks of the current quarter the death-rate has averaged 25·9 per 1000, whereas the mean rate during the same period did not exceed 16·1 in London and 17·3 in Edinburgh. The 187 deaths of Dublin residents from all causes during the week under notice were 25 fewer than the number in the previous week, and included 12 which were referred to the principal epidemic diseases, against 17 and 21 in the two preceding weeks. These 12 deaths were equal to an annual rate of 1·6 per 1000, the rate from the epidemic diseases during the same week being 1·6 in London and 1·9 in Edinburgh. Of the 12 deaths from these epidemic diseases in Dublin last week, six resulted from whooping-cough, three from "fever," two from measles, and one from diarrhœa, but not any from small-pox, from scarlet fever, or from diphtheria. Compared with the numbers in the two preceding weeks, the deaths from whooping-cough, from measles, and from diarrhœa showed a decline, while those referred to "fever" were in excess. The 187 deaths registered during the week included 28 of infants under one year of age and 59 of persons aged 60 years and upwards, both these numbers being lower than the corresponding numbers in the preceding week. Two inquest cases were registered, but no death was attributed to violence; while 84, or 44·9 per cent., of the deaths occurred in public institutions. The cause of one death in Dublin last week was not certified; in London all the 1393 deaths were duly certified, while in Edinburgh the proportion of uncertified deaths was 3·2 per cent.

THE SERVICES.

Royal Navy Medical Service.

The following appointments have been notified:—Fleet-Surgeons: C. Bradley to the *Cæsar*, on recommissioning; and R. H. J. Browne to the *Temeraire*. Staff-Surgeons: P. H. Bannister to the *Skirmisher;* and G. E. Duncan to the *Sentinel*, on recommissioning. Surgeon: A. S. Bradley to the *Hussar*, additional and on recommissioning.

Royal Army Medical Corps.

Lieutenant-Colonel Tom P. Woodhouse to be Brevet-Colonel under the provisions of Article 35 and 307 of the Royal Warrant for Pay and Promotion, 1907 (dated April 28th, 1909).

Major W. Hallaran, who has returned from Jullundur, has been appointed to the London District.

Reserve of Officers.

The appointment of Captain Herbert E. Dalby, of the late Royal Army Medical Corps (Militia), which was notified in the Gazette of Nov. 17th, 1908, is cancelled.

Territorial Force.

Royal Army Medical Corps.

3rd London General Hospital: Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel John Adams, from the 21st Middlesex (The Finsbury) Volunteer Rifle Corps, to be Lieutenant-Colonel with the honorary rank of Surgeon-Colonel, with precedence as in the Volunteer Force (dated April 1st, 1908). William Kirman Pauli, late Surgeon-Lieutenant, 3rd Volunteer Battalion, The Royal Fusiliers (City of London Regiment), to be Major (dated March 31st, 1909).

2nd Western General Hospital: Lieutenant-Colonel Alfred H. Young resigns his commission (dated Feb. 27th, 1909). Major William Thorburn to be Lieutenant-Colonel (dated Feb. 28th, 1909). Frederic Hibbert Westmacott to be Major (dated Feb. 28th, 1909).

For attachment to Units other than Medical Units.—The undermentioned officers, from the Westmorland and Cumberland Imperial Yeomanry, are appointed to the corps, with precedence as in the Imperial Yeomanry (dated April 1st, 1908): Surgeon-Major Joseph Edward Bowser to be Major; Surgeon-Lieutenant John Livingstone to be Lieutenant. Lieutenant Thomas Price Thomas, from the Royal Army Medical Corps (Militia), to be Lieutenant, with precedence as in the Militia (dated March 11th, 1909).

Unattached List for the Territorial Force.—Surgeon-Captain Henry Waite, from the 2nd (Leeds) Yorkshire (West Riding) Royal Engineers (Volunteers), to be Surgeon-Major (dated Feb. 4th, 1909).

Volunteer Corps.

Rifle: The Cambridge University Volunteer Rifle Corps: Surgeon-Captain (Honorary Lieutenant in the Army) Robert W. Michell, not having signified his wish to serve in the Territorial Force, is struck off the strength of the corps (dated March 31st, 1908).

Royal Army Medical Corps Examination.

An examination of candidates for not less than 20 commissions in the corps will be held on July 28th and following days. Applications to compete should be made to the secretary, War Office, S.W., not later than July 19th next The presence of candidates will be required in London from July 26th.

Correspondence.

"Audi alteram partem."

CONVULSIONS UNDER CHLOROFORM.

To the Editor of The Lancet.

Sir,—The occurrence of convulsions during chloroform syncope, referred to by Dr. A. E. Russell in his Goulstonian lectures, is a matter of considerable interest which has not received the attention it deserves. 15 years ago,[1] before the Society of Anæsthetists, I remarked upon the similarity of the symptoms in certain cases of death under chloroform to those occurring in death from failure of the circulation from other causes—e.g., sudden hæmorrhage and cardiac syncope. I argued from this that deaths under chloroform were due to failure of the circulation and not to gradual paralysis of the respiratory centre. In a continuation of that paper[2] I suggested that the presence of convulsions or muscular disturbance in chloroform fatalities was a further argument in favour of sudden paralysis of the circulation being the cause of death.

The object of the two papers and others[3] subsequently published was to bring out the fact that the signs of failure of the circulation under chloroform are identical with those present under similar conditions occurring during consciousness—that is, exaggerated respirations, pallor and dilated pupils, with, in certain cases, muscular disturbance of a spasmodic character. The non-appreciation of this obvious fact is responsible for many of the deaths from chloroform. Gradual respiratory paralysis as the sole cause of death under chloroform has been so insisted upon that the significance of too free respiratory movements is apt to be overlooked. Secure in the belief that gradual cessation of respirations is the main danger, the chloroformist may easily take the free respirations as a sign of well-being. This failure of the circulation invariably sets in at an early stage of the inhalation, just at the period when the attention of the administrator is most likely to be distracted by preparations for the operation. Under these circumstances, the exaggerated respiratory movements pass for normal breathing; it is their sudden cessation which attracts notice to the grave condition of the patient. The only treatment for these cases is artificial respiration, so applied as to exert vigorous compression of the chest. The object of this is to stimulate the heart and to raise the blood pressure, not to get air into and out of the lungs. This, too, is often misunderstood, for even if the serious condition of the patient is recognised while respiration continues, nothing is done because artificial respiration seems uncalled for when free breathing is present. Thus the only chance of resuscitating the patient is lost, for to be effective artificial respiration must be begun on the first onset of exaggerated respirations.

Dr. Russell suggests that "in cases of chloroform syncope the anæsthetic would doubtless negative the spasm." This is true only to a limited extent and is governed mainly by the degree of general anæsthesia present when the syncope occurs. The valuable list of chloroform accidents collected by The Lancet Chloroform Commission contains a number of cases in which muscular disturbance was present. These varied from mere trismus or slight muscular rigidity to pronounced convulsions and opisthotonos The factors which chiefly determine the extent of the muscular action are: the stage of general narcosis at which the syncope sets in; the suddenness and completeness of the arrest of circulation; the presence of any cause calculated to facilitate the induction of cerebral anæmia, such as the sitting posture; the condition of the muscular system as regards vigour and stability. The following cases taken from THE LANCET list illustrate the influence of the above conditions.

---

[1] The Mechanism of Death under Chloroform, The Lancet, Nov. 17th, 1894, p. 1148.

[2] Ibid., Sept. 11th, 1897, p. 656.

[3] A Case of Death under Chloroform, The Lancet, July 30th, 1898, p. 260; Accidents from Chloroform Anæsthesia, Medical Chronicle, 1906.

Case 55, a male, aged 30 years; operation, removal of necrosed bone from finger; duration of administration, from three to four minutes. Sitting posture. Symptoms: "Raised hands and trembled, kept spitting at the lint; appeared about to vomit. Suddenly he was violently convulsed as if in an epileptic fit." Here are associated an obviously slight degree of narcosis; the sitting posture conducive to cerebral anæmia; a young man with only a trifling ailment, therefore probably with vigorous muscular system. The arrest of circulation from the syncope produces "violent convulsions."

Case 83, a girl, aged 12 years; operation for necrosis of tibia. Symptoms: "Deadly pallor, twitching of muscles about mouth, eyes rolling up, pupils dilated, stertorous breathing." In this instance the syncope came on at a much more advanced stage of the anæsthesia, and the patient was presumably recumbent; the muscular disturbance was therefore slight.

These two cases are examples of many set forth in THE LANCET report and show the two extremes of muscular disturbance induced by chloroform syncope.

I have heard about, and been asked the treatment for, cases in which there occurs rigidity or fixation of the respiratory muscles in a condition of expiration. I have never seen any such symptoms, but imagine that such a condition is merely part of a general muscular action due to cerebral anæmia. It is most probably the contraction of the muscles immediately preceding dissolution. No doubt it is equivalent to the "sudden stiffening of all the muscles" which is referred to by Dr. Russell as exhibited by cats, when the cerebral circulation is interrupted. The only treatment under such circumstances is to attempt to restore the circulation, but at such a late stage there is very little chance of success except by direct massage of the heart. In this connexion Dr. Russell's remarks about the length of time the brain and heart can withstand the loss of circulation are very interesting and encouraging. If the brain can survive the loss of circulation for five minutes and the heart a much longer period of arrest, surely chloroform accidents should be more amenable to treatment? That they are often so hopeless is due to the fact that the symptoms of danger are not recognised sufficiently early. If the brain can do without circulation for five minutes the basal centres which are more fundamental in their nature should survive still longer. We are thus confronted by the fact that the respiratory centre, for instance, may be exhibiting energy for some minutes after cessation of the circulation; that the patient may, and no doubt does, continue breathing or making respiratory efforts for some time after the heart has ceased to beat or at least to beat effectively. This possibility makes it all the more necessary for the respirations to be studied carefully during chloroform administration, in conjunction with the circulation. Any alteration in the rhythm or character of the respiration, especially of the nature of an acceleration, should be viewed with suspicion and be checked by observation of the circulation. Failure of the circulation is indicated at once by exaggeration of the respirations, with which are associated pallor and dilated pupils. These symptoms may set in at any period of the inhalation, but almost invariably occur within the first few minutes of the administration.

I think that a proper appreciation of the first signs of danger under chloroform and prompt treatment will do more to diminish the number of fatalities than the use of any apparatus, however ingenious.

I am, Sir, yours faithfully,

ALEXANDER WILSON, F.R.C.S. Eng.,
Honorary Anæsthetist, Manchester Royal Infirmary;
Honorary Lecturer on Anæsthetics,
University of Manchester.

Manchester, April 20th, 1909.

THE UNIVERSITY OF LONDON AND THE STUDY OF ANTHROPOLOGY AND ETHNOLOGY.

To the Editor of THE LANCET.

SIR,—In the article on "An Imperial Bureau of Anthropology" published in THE LANCET of April 10th, you say that "the Universities of Cambridge and Oxford have established boards of anthropological studies, with the power of granting diplomas to those who have qualified by studies under their direction in prehistoric and historic anthropology and ethnology (including sociology and comparative religion, physical anthropology, and psychological anthropology). While the students at Oxford and Cambridge are thus provided for, no opportunities are given to students in London."

May I point out that for the past few years, owing to the munificent generosity of Mr. Martin White, the teaching of the subjects to which you refer has been carried on in London by two University professors of sociology, Mr. L. T. Hobhouse and Dr. E. A. Westermarck, and by a University lecturer in ethnology, Dr. A. C. Haddon (who holds a similar post at Cambridge). Sociology forms part of the curriculum, as an optional subject, both for the B.A. honours degree in philosophy and for the B.Sc. honours degree in economics, and the London classes in this subject are flourishing. The University is at the present moment making efforts to secure a permanent endowment for ethnology similar to that which has already been provided for the chairs of sociology, and for the past 12 months the Senate have been in communication with the Colonial Office with a view to ascertaining whether that Office would be able to assist and coöperate with them in the establishment of an ethnological department on a satisfactory basis.

With reference to the concluding paragraphs in your article, I beg to point out that the University has recently established a board of studies in ethnology.

I am, Sir, your obedient servant,
W. J. COLLINS, Vice-Chancellor.

South Kensington, S.W., April 27th, 1909.

*** We are glad to know from Sir W. J. Collins that a board of studies in ethnology has now been established by the University of London; in the last issue of the Calendar of the University (1908-09, p. 153) it is stated this board "is not yet instituted."—ED. L.

THE VASO-MOTOR THEORY OF EPILEPSY.

To the Editor of THE LANCET.

SIR,—In his admirable [illegible] above subject Dr. Alfred to a work of mine in w views. He says: "Francis Hare maintains that the explanation of the aura is to be sought in the peripheral vaso-constriction which he postulates as preceding the cardiac inhibition."[1] The reference is accurate but incomplete. Some epileptic auræ felt at the periphery are certainly due to peripheral vaso-motor action, whether constrictive or dilative. In proof whereof I have adduced the following paragraphs from Hilton Fagge and Trousseau respectively.[2] "The patient perhaps experiences a sensation of coldness or weight in a limb; and the part is found on examination to be pale and cold to the touch, and to have its sensibility distinctly blunted" (Fagge). Others of the vascular changes may be peripheral and dilative. "A local determination of blood may occur in the finger, for instance, causing it to swell, reddening the skin and rendering it successively within a very short time red, and of a more or less deep violet colour. . . . The swelling is real, not apparent, for rings previously easy suddenly become too tight for the fingers" (Trousseau). So much for peripheral vaso-motor action as explaining some auræ felt at the periphery.

That, however, is but one side of the subject On the same page *I go on to say*: "But many auræ are unas [illegible] with appreciable objective changes in the part who seem to arise. Then it is not unnatural to believe that invisible vascular changes, similar in character to the visible peripheral vascular changes just described, are taking place in the cerebral centres and are the immediately responsible factors. On this view, we can understand many of the auræ of the special senses, observable also in migraine; and we can appreciate the time differences between the auræ of epilepsy and of migraine."

I am, Sir, yours faithfully,

Upper Norwood, April 25th, 1909. FRANCIS HARE.

THE PROXIMATE FACTOR OF DELIRIUM TREMENS.

To the Editor of THE LANCET.

SIR,—In my letter which appeared in THE LANCET of April 17th, p. 1136, I stated that "there are many more regular or continuous drunkards than periodic drunkards, but the latter are just as liable to suffer from delirium tremens as are the former." Dr. F. Hare considers that the opinion I express is not in accordance with generally received views.

It is difficult to determine what the generally received views are, for a reference to the works of various writers will demonstrate that opinions differ on the point. I base my opinion on the histories of 896 cases of inebriety, the records of persons who have been admitted into the Dalrymple Home Retreat. Of this number 669 were regular drinkers, 215 of whom had suffered from delirium tremens. The periodic inebriates numbered 227, of whom 74 had had delirium tremens. In both classes the delirium tremens percentage works out at about 32. By periodic inebriate I mean persons who at regular or irregular intervals give way to outbursts of alcoholic excess; between the outbursts they are either temperate or are total abstainers. The 669 regular drinkers mentioned above are entirely composed of the soaker and the chronic alcoholist who manifests occasional outbursts—types referred to by Dr. Hare. I have found that these persons, as well as the periodics, can have their liquor cut off suddenly with perfect safety.

Dr. Hare further finds that my statement is opposed to his experience at the Norwood Sanatorium. His experience there, unless I misread his report, has consisted of 13 cases of delirium tremens which occurred among some 200 admissions during a period of about two years, a number which appears to me totally insufficient as a basis for contention.

I am, Sir, yours faithfully,

April 26th, 1909. F. S. D. HOGG.

THE RÔLE OF THE SALIVA IN THE TRANSMISSION OF TUBERCLE.

To the Editor of THE LANCET.

SIR,—In connexion with the instructive article by Dr. N Neild and Dr. E. V. Dunkley on "The Rôle of the Saliva in the Transmission of Tubercle"[1] the following may be of interest to your readers. A patient attending the inoculation department at the London Hospital, suffering from lupus of the nose and naso-pharynx, is by trade an envelope folder. I questioned her to-day about the details of her work and find that her duties are folding, gumming, and sticking envelopes. The gum is applied with a brush and the flaps are then pressed down; should there be any excess of gum pressed out along the flaps, this has to be licked off with the tongue of the folder so that the envelopes shall not stick together when piled up. It seems, therefore, that if tubercle can be transmitted by licking envelopes the danger may be to the sender as well as to the receiver.

I am, Sir, yours faithfully,

York-street, Portman square, W. G. T. WESTERN.

THE DISAPPEARANCE OF MR. JOHN DAVIDSON.

To the Editor of THE LANCET.

SIR,—Among the documents found since the disappearance of Mr. John Davidson was one in which he speaks of his inability to face the effects of cancer. His family wish, in the circumstances, to discover on what grounds he based his belief that he was suffering from this disease, and I write on their behalf to ask if you will allow me, through your columns, to request any medical man whom Mr. Davidson might have consulted in the last few years to communicate with me at this address if he feels himself free to do so.

I am, Sir, yours faithfully,

GRANT RICHARDS.

36, Roland-gardens, S.W., April 23rd, 1909.

AN AMBULANCE SERVICE FOR THE METROPOLIS.

To the Editor of THE LANCET.

SIR,—I think that if Mr. H. Nelson Hardy (who writes under the above heading in THE LANCET of April 24th) had read with care the Blue-book containing the report of the Ambulance Committee, or your article upon it in THE LANCET of April 3rd, he would have seen that the question of providing an ambulance service for London, if such a service is to be efficient, economical, and useful, is hardly to be solved by the Home Office authorising the purchase of ambulances by the police. Ambulances have to be housed, maintained, and manned, telephonic communication must be so established as to enable them to be speedily summoned, and all this has to be paid for. Also, as your article makes clear, the service in order to be of real utility will have to be so arranged that it can deal not only with street accidents but with those on private premises, and with other cases which, though needing removal by ambulance, are not accidents. The committee was pretty fully informed as to the excellent work carried out in the City under Captain Nott Bower; it had his evidence and that of a large number of other witnesses, including police surgeons and other members of the medical profession; it had visited and examined on the spot the systems in use at Manchester and Liverpool; it had detailed information from a number of provincial boroughs, and also from Paris, Berlin, New York, Boston, and other foreign cities. The question of police administration is thus summed up in his memorandum to the report by Sir William Collins, who says on this point: "There is much to be said for the police undertaking the duty. If the Metropolitan Police were a municipal force, as in the City and the provinces, there can be little doubt that the duty would fall to them. As it is, there appears to be no disposition on their part to undertake it, and my colleagues consider it undesirable for various reasons to assign this additional work to them." There are many reasons which render it highly desirable that the Metropolitan Police should continue to be under the control of the Home Office and not of the London County Council, but it seems to me that London would hardly acquiesce without protest in the Home Office being authorised by Act of Parliament to levy such a rate as would be required for duties not connected with the essential functions of the police, or that it can be desirable for a body responsible only to that department to control an enlarged ambulance service. If the proposed service were confined to the removal of those suffering from street accidents within the strictly metropolitan area it might be different.

I am, Sir, yours faithfully,

April 26th, 1909. E. A. A.

CARDIFF MEDICAL SOCIETY.—The annual address of this society will be given in the lecture-hall of the Young Men's Christian Association on Friday, June 4th, at 3.30 P.M., and will be delivered, as was announced in THE LANCET of April 24th, by Dr. J. Lucas Championnière of Paris, President of the International Surgical Society, who has taken as his subject the Modern Treatment of Fractures. The annual dinner of the society will be held on the same evening at the Royal Hotel, Cardiff, at 7.30 P.M. Dr. Lucas Championnière will make the presentation of the Lynn Thomas and Skyrme Fund after the dinner. All members of the profession are cordially invited to be present at the dinner, and as the occasion is a special one it is hoped that as many as possible will avail themselves of the opportunity. Tickets (7*s.* 6*d.* each) can be obtained from the honorary secretaries, Mr. F. P. S. Cresswell, 24, Windsor-place, Cardiff, and Dr. William Martin, 17, Windsor-place, Cardiff, and it is requested that application for them be made as soon as possible, and in any event not later than May 28th.

---

THE DRAINAGE OF CAIRO.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

(Continued from p. 1210.)

A COLLECTION OF BARREN SCHEMES.—SELF-CLEANSING SEWERS AND THE SEPARATE SYSTEM.—THE SCHEME THAT HAS BEEN FINALLY ADOPTED.—THE EXCEPTIONAL FACILITIES OF CAIRO: LITTLE RAIN AND LAND WITHOUT PURCHASE.

Cairo.

CAIRO, especially the European quarter, is almost flat and therefore cannot be drained by gravitation. Many schemes have been prepared so as to overcome this difficulty, but none of them were carried out. Ultimately it was determined to seek the best available technical advice. For that purpose Mr. C. Carkeet James, member of the Institute of [illegible] distinguished himself notably [illegible] the drainage of Bombay, was [illegible] of the main drainage department at Cairo. He was given a couple of years to study the situation, which he soon found to be so different from what generally exists that past experience helped him little. He faced the situation, however, with courage and ingenuity, and after a while began to prepare schemes for the drainage of Cairo; but his schemes might be likened to ninepins. Like the many proposals that had preceded his coming, they were no sooner put up than they were knocked down. His first scheme was rejected because the sewage farm which he proposed to establish was on land that might in the course of time be required for building purposes, and his pumping station was too near to dwelling houses. The site for the sewage farm in the second scheme was that which has now been accepted, but the pumping station, though away from existing houses, might prove, so it was thought, a nuisance to prospective buildings. The proposed position of the pumping station also wrecked the third scheme; and when in the fourth scheme Mr. Carkeet James sought to avoid these objections by going to the other side of the Nile the suggestion was rejected because of the difficulty and cost of carrying the sewage under the Nile by means of a syphon. A fifth scheme was thrown out because the new sites selected for the pumping station and sewage farm were not considered any improvement on those that had been previously proposed. The sixth scheme did away altogether with a sewage farm and established sewage purification works instead, discharging the purified sewage into the Nile. But there was a lack of faith in the process of purification and objections were raised to the discharge of sewage, whether purified or not, into the Nile. Schemes 7 and 8 shared the fate of their predecessors, being condemned because no satisfactory place for the pumping station had been found. The ninth scheme was only objected to on the ground of expense and the difficulty of getting sufficient water. The tenth scheme was rejected because it was too expensive, and it was held to be unnecessary to employ, as proposed, two different systems of raising sewage—namely, the vacuum and the compressed air systems. It was not till he had reached his eleventh scheme that Mr. Carkeet James contrived to reconcile the many conflicting interests which had till then successfully thwarted his various plans.

The main difficulty, as already stated, has been that the populous part of Cairo is built on a plain and therefore cannot be drained by simple gravitation to a sufficient distance to reach a conveniently situated sewage farm or any works for the disposal of sewage. On the other hand, it is possible to drain one suburban part of the city by gravitation to a pumping station, and this is defined in the scheme now accepted as the "gravitation area." The more important part of the city is divided up into small sections. In the centre of each section of what is to be called the "sectional area" there will be a Shone ejector. This system is well known and is applied in many foreign and some British towns. Theoretically its great advantage is that of giving to absolutely flat districts sewers which nevertheless have so efficient a fall as to be self-cleansing. Perhaps it may be said that at present the majority, or in any case a very large portion, of the sewers which rely only on gravitation to assure the flow of the sewage are not self-cleansing. Though the ground may be absolutely level a sufficient fall can always be given to a sewer by digging down into the earth deeper and deeper, on the one condition, however, that the sewer in question shall not be very long. Therefore the success of the Shone system depends on placing the ejectors near enough to each other. It is well known that the *ejector is a drum-shaped receptacle* which works automatically by pneumatic pressure. In the case of the English Houses of Parliament it was found that there was not a sufficient fall to drain them efficiently into the Westminster main sewer, and so the required fall was created by digging the drains down to a much lower level than the great sewer that passes by Westminster Bridge. This done, a Shone ejector was placed at the end of the system to receive all the drainage of the Houses of Parliament and raise it up again to a different height to be discharged into the Westminster main sewer. This is how it is proposed to drain at Cairo a thickly populated area measuring 1721 hectares. The success will depend on employing a sufficient number of ejectors, otherwise they would have to be placed so far apart that it will not be possible to give a steep enough gradient to the sewers feeding these ejectors for the sewers to be self-cleansing. Mr. Carkeet James, however, does not complain of any stinting in this respect. At Toulon, I remember many years ago, after the cholera scare, it was proposed to employ the same system, but the scheme, as laid down, would have worked badly because there were not sufficient ejectors.

The question of an efficient fall in the sewers is of greater importance in oriental than in English towns. In England it is very generally thought that a gradient which will give to the flowing sewage a velocity per second of 2 feet or 2½ feet (0·60 to 0·75 metre) is enough to prevent the formation of deposits on the sides of the sewers; in other words, to insure self-cleansing conditions. But in Cairo, where there will be practically no rainwater and far more extraneous matter than is the rule in England, this would be quite inadequate, and the sewers might not only be dirty but even blocked up. Therefore the scheme adopted lays down as a fundamental principle that all sewers, whether running full or half full, shall have a minimum velocity of 1·05 metres, or nearly 3½ feet per second. This should be strong enough to push forward a stone of the ordinary size of street macadam.

The power station will be situated at Pont Sahel at the commencement of the Ismailia Canal. This faces the most populous part of the city and is conveniently near to the district where the ejectors will be employed. As the power to be generated is compressed air it will occasion no nuisance whatsoever. Nevertheless, it would have been well if this power station had stood on the same premises as those occupied by the general scavenging and road department. This is the case at Sonthampton where the Shone system obtains, and the advantage is that the compressed air is used for many other purposes besides providing the motive force to raise the sewage out of and above the ejectors. It saves much labour for all the smithy work necessary to mend the town rolling stock, &c., as bellows are no longer needed. It is only necessary to touch a tap to obtain a continuous discharge of air into the fire and the force of this blast can be regulated to a nicety. Again, all the dry food, such as chopped hay or oats, given to the numerous horses, mules, &c., employed for the municipal services, is beautifully cleaned by discharging into it a current of compressed air. All the dust and impurities are blown away and absolutely pure corn and fodder given to the animals. This has so improved the horses of the Southampton municipality that they have become the pride of the town. The advantage of municipal enterprise is often somewhat to seek, but, at any rate, by it totally different services can be welded together to their mutual advantage. Thus, at Cairo the sewage scheme might be made to reduce the cost and improve the condition of the smithies, while also securing better food, therefore better health, for all the horses, mules, and donkeys employed.

The outfall of the sealed—that is, the air-tight—iron mains which receive the contents of the ejectors is not to be the general outfall of the entire system at Cairo; that is at the Pont Chamra, and into the head or commencement of the main collector which is to receive the sewage from the suburban districts that are to be drained by gravitation only. This main collector will follow the road to Teftiche-el-Koubbeh, thence along the Materieh road to Ein-el-Chams, and then it will run by the side of the Cabel canal to a point one kilometre east of the village of Kafr-el-Gamous. This collector commences at a depth of 3·03 metres. When it reaches the canal it is 4·05, but quite at the end of its course and for only a short distance, it descends to a depth of ten metres. It will be a circular sewer of 1·60 metres in diameter, with a minimum thickness of concrete of 0·35 metre and an external breadth of 2·32 metres. Into this main sewer will be drained by gravitation the old and new barracks, and all the buildings of the suburbs of Abbassieh, Demerdache, Koubbeh, Heliopolis Oasis, Zeitoum, Helmieh, Matarieh, and Ein-el-Chams, covering altogether 1258 hectares, and this is to be done immediately. Ultimately, another neighbouring area of 1775 hectares will be added. With very few exceptions the sewers will be laid at a gradient that will give a velocity of 3½ feet per second to the sewage. These branch sewers will vary from 8 to 20 inches in diameter. The main collector will be 13 kilometres in length, and at its end a great pumping station will be built to lift the sewage up and force it forward in a rising main so that it may travel yet another 11,670 metres. It will then reach the sewage farm, which is situated in the desert 26 kilometres north of Cairo. These last 11 kilometres represent the length of what is called the rising main. If it is constructed of cast iron or steel its diameter will be 36 inches (0·914 metre) and the flow 4·24 feet (1·292 metres) per second. If it is made of reinforced concrete the diameter will be 38 inches and the velocity 3·31 feet per second. The cement is more susceptible to the erosive action of the sand in the sewage, and this reduces the velocity of the flow.

The purification works will be at the foot of sand-hills to the east of the Khanka lunatic asylum at 26 metres above the river level, with a gentle fall in a southerly direction. The soil here has been analysed and found admirably suited for the purpose, and probably it will only be necessary to pass the sewage once through liquefying tanks before using it for irrigation purposes. Not only will the soil purify the sewage but it will grow almost any crop that flourishes in Egypt. A thousand feddans or acres will be brought under cultivation and should produce a revenue of £E.15 per feddan. Mr. Carkeet James, however, judging from his Indian experience, maintains that a very much larger income might be obtained. Indeed, if properly managed the sewage farm should. according to some optimistic estimates, bring in sufficient profit to cover the working expenses of the sewage scheme. In one respect Cairo is favoured among cities. It has its disadvantages, but where in Europe will any large town be found that has close to its gates such a vast expanse of unoccupied, unowned land all ready to be converted, without the cost of purchase, into sewage farms, rubbish depôts, and sites for isolation hospitals, and so on? In England especially the difficulty of dealing with sewage is that of finding land for sewage works, but the same difficulty occurs in the neighbourhood of many Continental capitals. What student of these questions has not followed with thrilling interest the homeric struggle of Durand Clay and his fellow disciples of the *tout à l'égout* doctrine to obtain land enough to create sewage farms round and about Paris. More than 40 years ago this struggle was commenced and it is not terminated yet. But in the desert which is so close to Cairo there are no proprietors of valuable land and of house property to organise demonstrations, to present petitions, to run candidates for Parliament, all so as to stop the execution of a drainage scheme which, as was the case near Paris, they imagined might cause a nuisance in their neighbourhood. At Cairo it is only necessary to go about 11 kilometres beyond the area to be drained to reach a spot in the desert where no one owns property and where no one can protest. For this exceptional facility the inhabitants of Cairo should be most thankful.

Again, Cairo enjoys the advantage of a very small rainfall. According to the carefully collected observations of the Survey Department the average rainfall in Cairo for the last 11 years is 23·50 millimetres. The maximum and minimum annual rainfall were 51·10 and 4·10 millimetres respectively. During the years in question there have been only eight occasions when the amount of rain that fell on any one day exceeded 10 millimetres (0·4 inch). On three occasions 20 and on one occasion 24·60 millimetres fell within 24 hours. Therefore the very heavy rains are extremely rare, and it would be a waste of money to provide big sewers to carry this large volume of water away. Also, it is an admitted principle that it is only the early rush of water, the first and small amount of rain, that is foul. The surface dirt is removed at the commencement of the downpour and then the water runs clear. Thus a storm overflow into the nearest river is allowed in almost all schemes of drainage. Again, if the sewers were big enough to carry away all the rain water they would be too big for the ordinary sewage. There would not be sufficient water in such large sewers during the dry weather to insure a self-cleansing action. Therefore the separate system is especially suited to the conditions prevailing at Cairo. In the neighbourhood of the Opera House an area of 290 hectares has already been drained and has its sewer outfall in the Ismailia Canal, near Pont Limoun, where the chief railway station stands. These surface drains bring water from the washings of the markets and the asphalted streets. Such water is often very foul and causes considerable nuisance. These existing drains, though not perfect and providing a velocity of only 2 feet per second, are considered good enough with slight repairs and alterations to be preserved for surface drainage.

At the outfall of this old drain the existing sump or catch-pit will be enlarged so as to arrest the silt and enable the drains to run dry, thus preventing their becoming a breeding place for mosquitoes. When the amount of this surface drainage and rain-water drainage does not exceed half the calculated maximum of flow from the drainage area it will be pumped up into the sealed sewage main, passing along the Sharia Abbas and connected with the Shone system, which in its turn discharges into the main collector, commencing at Pont Chamra and connected with the combined or gravitation system. But if through heavy rain this amount is exceeded then a storm overflow into the Nile is provided.

Without entering into all the other details, for they are based on the same principle, it will be seen at once that we have here an inconsistency. The great advantage of what is called the separate system is that it separates. When dealing only with sewage and slop water—in other words, when the rain water is excluded—it is then easy to calculate with sufficient precision to cover all practical purposes what will be the quality and the quantity of sewage arriving hour per hour at the sewage outfall. It is then possible to decide how to utilise this sewage. But if the rain water is admitted then the quantity and quality of the sewage become very untrustworthy. Now at Cairo it is proposed to establish the separate system, but the advantage in respect to the treatment of sewage which this affords is lost by allowing such rain water as there is to be pumped into the sealed mains connected with the Shone ejectors, and further discharging these sealed mains into the general collector that also receives rain water. Thus, and up to the point when the storm overflows come into action, the rain water will reach the sewage farm, having first mixed with, diluted, and altered the nature of the normal sewage. In England or any other country where rain is abundant and frequent this would be a very serious objection. In Cairo, where there is so very little rain, it may prove an advantage. The fact that rain falls so rarely increases the likelihood that the first wash of the rain will be exceptionally foul. It is therefore an advantage that the first rush of rain should go with the sewage to the sewer outfall and not flow into the river. Also, an occasional discharge of rain water into the main collector will be of service as an extra flush in case the ordinary flow should fail in its self-cleansing action. To judge, however, from the levels given, and the size of the sewers proposed, there is every reason to believe that in this respect the scheme is likely to prove satisfactory. If the sewage reaches the sewer and is accompanied with a sufficient volume of water there is but little doubt that it will be borne away at once and soon reach the sewage farm, where it will be placed beyond the possibility of injuring the population of Cairo. The laying down of such a general scheme of drainage is by far the most difficult and expensive part of the work, yet the health of the population probably depends more on the detail of the connexion between the houses and the sewers than on the sewers themselves. It is easier to have a sanitary house draining into an ill-constructed sewer than it would be to maintain the health of people living in insanitary houses that are drained into model sewers. Therefore, it will now be necessary to study the domestic details of application before a definite opinion can be formed as to the likely success of this scheme.

(*To be continued.*)

CHOLERA AND PLAGUE IN RUSSIA AND THE NEAR EAST.

(FROM THE BRITISH DELEGATE ON THE CONSTANTINOPLE BOARD OF HEALTH.)

Cholera in Russia.

THE following figures, relating to the further progress of cholera in Russia, are in continuation of those published in my last letter on the subject.[1] Between Feb. 8th (21st) and 14th (27th) there were 110 cases of the disease, with 35 deaths, distributed as follows: in St. Petersburg, 88 cases and 25 deaths; in the St. Petersburg government, 13 cases and 6 deaths; in the Yaroslavl government, 5 cases and 2 deaths; in the Tula government, 3 cases and 2 deaths; and in the Don Cossack territory, 1 case with no death. Between Feb. 15th (28th) and 21st (March 6th) there were 97 cases with 46 deaths; of these 84 cases and 39 deaths occurred in the town of St. Petersburg, and the remainder were distributed between the governments of St. Petersburg and Yaroslavl and the Don Cossack territory. Between Feb. 22nd and 28th (March 7th and 13th) there were 51 cases and 19 deaths; of these 49 cases and 18 deaths occurred in St. Petersburg and the remainder in the governments of St. Petersburg and Yaroslavl and in the town of Kharkof (a single case, in a traveller from the north of Russia). Between March 1st (14th) and 7th (20th) 45 cases and 8 deaths were registered, all of which occurred in the capital or in the government of Yaroslavl. In that week the town of Rybinsk was declared "threatened" with cholera and the Don Cossack territory was declared free from the disease. Finally, between March 8th (21st) and 14th (27th) only 25 cases of cholera, with 5 deaths, were recorded, all in St. Petersburg, and between March 15th (28th) and 21st (April 3rd) only 10 cases, with 3 deaths, also confined to the capital.

Cholera and the Water-supply of St. Petersburg.

This marked reduction in the numbers of cases and deaths in the city of St. Petersburg and the apparent disappearance of the disease from other parts of Russia are satisfactory as far as they go, but it is evident that the infection still lingers in the capital, at any rate; the approach of warmer weather is not far off and a fresh revival of the disease in the coming summer must be regarded as almost inevitable. Some leading Russian newspapers have recently contained somewhat bitter comments on the measures, or rather on the comparative lack of measures, taken by the responsible authorities to deal with the outbreak. They point out that St. Petersburg in particular has no proper water-supply, and that the prevalence and continuance of the disease there have been mainly due to the fact that the drinking water supplied to the people has been seriously contaminated with the infection of cholera. That water is obtained directly from the river Neva. According to a communication recently made to the Duma and quoted in the journals the water is taken from the river at a point above which the stream has already been polluted by receiving the drainage of a large population. As much as 15,000,000 *vedros* (a *vedro* is equal to 2·7 gallons) of sewage is said to enter the river above the point in question. The water is said to be distributed to the town either unfiltered or imperfectly filtered. For some time past a scheme has been talked of, under which water would be brought to St. Petersburg from the Lake of Ladoga. The distance of the lake from the city is approximately 30 miles and the cost of executing the proposed scheme is estimated at about 30,000,000 roubles (say £3,000,000 sterling). It is also reckoned that at least several years would be required to carry out the scheme in its entirety, and in the meantime, it is pointed out, there is urgent need of finding some temporary and less costly method of dealing with the evil, though, with one exception, no very definite proposal has yet been made as to the form the temporary measure should take. There can be no doubt that both the question of the water-supply and that of the drainage of St. Petersburg involve very difficult problems. The main part of the city lies practically at sea-level; when high westerly winds prevail the waters of the Gulf of Finland are driven up, and a great part of the city is inundated. The population of the city is now put at 2,000,000 inhabitants, requiring about 25,000,000 *vedros* of water per day. The same quantity of liquid sewage is discharged into the Neva every day. It is impossible to render this harmless, and in the meantime it is impossible to obtain the main water-supply from any other source. Any measure that would tend to diminish even temporarily this obviously immense danger should prove welcome, and an ingenious suggestion was recently made by Dr. P. P. Bakaleinik, in a paper read before the Russian National Health Society. This suggestion is based on the obvious fact that the bulk of the sewage matter reaches the river during the day and relatively little during the night. Samples of water were taken from the middle of the Troitski bridge over the Neva at different hours of the day and in the night at 2, 4, and 6 A.M., and were analysed chemically and bacteriologically. It was found that while the specimens taken during the day contained an appreciable quantity of urea (*sic*) and ammonia and of suspended foreign matters, those taken between the hours of 2 and 6 A.M. contained none of these and were also free from the presence of cholera vibrios. (It appears to be implied, though it is not stated, that such vibrios were present in the day specimens.) The proposal made is therefore to collect the daily supply of water from the Neva in the early hours of the morning and store it in large reservoirs, from which it would be distributed to the city. Three such reservoirs, in different parts of the city, would, it is thought, suffice. They could be constructed, it is said, in about ten weeks and would cost incomparably less than the Lake Ladoga scheme. Without a full knowledge of all the circumstances it is difficult to form an opinion as to the practicability of this proposal; it would seem at first sight to offer certain distinct advantages as a temporary palliative of a serious evil, but it may perhaps be doubted whether the practical difficulties—the cost and the time required to carry out the scheme—are not considerably greater than the author of the proposal considers them to be. It would, moreover, be unfortunate if a temporary scheme such as the one proposed should stand in the way of carrying out a radical and permanent scheme for supplying the Russian capital with a pure water-supply, free from all possible chance of contamination.

Plague in Bagdad.

The records of the outbreak of plague in Bagdad were brought down to Jan. 27th in my letter published in THE LANCET of Feb. 20th (p. 578). After that date only a single death ("found dead") was observed on Feb. 5th, and on Feb 23rd the town was declared "clean," and the measures in force on persons and river boats leaving Bagdad were suppressed. In all, 157 cases and 85 deaths were registered in Bagdad since May 7th, 1908.

Plague in Jeddah.

The outbreak of [illegible]
by the following fig
in THE LANCET of

Week ending March 7th	26 cases,	22 deaths.
,, ,, ,, 14th	20 ,,	16 ,,
,, ,, ,, 21st	16 ,,	16 ,,
,, ,, ,, 28th	18 ,,	15 ,,
,, ,, April 4th	9 ,,	8 ,,
,, ,, ,, 11th	5 ,,	6 ,,

The total number of cases of plague in Jeddah since the revival of the disease there on Dec. 12th last has been 176 and that of deaths 157. This year Yanbo has so far escaped infection.

Constantinople, April 15th.

THE Fifth International Congress of Medical Electrology and Radiology will be held at Barcelona on Sept. 13th to 18th, 1910.

---

WALES.

(FROM OUR OWN CORRESPONDENTS.)

Llandudno Water-supply.

THE reputation which has so long been held by Llandudno as a health resort is in no small measure due to the excellent manner in which the requirements of the town are looked after by the local sanitary authority. Included in the municipal undertakings are an isolation hospital and a refuse destructor, and during recent years a public slaughter-house has been established. The water-supply is obtained from two small lakes, Dulyn and Melynllyn, situated in the Snowdon district not far from Carnedd Llewellyn, a mountain peak nearly as high as Snowdon itself. It is nearly 20 years since the water was first brought to the town from these lakes, and neither the adequacy nor the quality of the supply has ever been questioned. There has now been completed an undertaking which will meet the needs of the district for many years to come. A second main has been laid at a cost of £33,000, so that it is possible to deliver daily 2,500,000 gallons. The watershed of the two lakes is not only under the control of, but it is owned by, the Llandudno council, so that the possibilities of pollution are extremely remote.

The House Physiciancy at the Swansea Hospital.

Upon the position of house physician to the Swansea Hospital recently becoming vacant applications were invited from medical practitioners, and when the board of management came to make the appointment it was found that one of the two applicants had withdrawn and that the other was a lady. Dr. R. C. Elsworth proposed that the appointment should be again advertised and that candidates should be confined to men. He expressed the opinion that the staff should either be all men or all women. After some discussion and the rejection of other proposals the resolution was carried. One of the resident posts has already been filled by a lady, but there appears to be some difference of opinion among the honorary staff as to whether this is desirable.

Low Temperature of Cardiff Schools.

At the last meeting of the School Management Committee of the Cardiff Education Committee attention was drawn to the very low temperature which prevailed in some of the public elementary schools at the time when the children first assembled in the morning. The schools had been supplied with charts for recording the temperatures in the class-rooms. These were taken under the supervision of the head teachers at 9 A.M., 12 noon, and 3 P.M. In his annual report the school medical officer (Dr. E. Walford) has recorded the maximum and minimum temperatures registered during the four winter months of 1908 in some of the infant schools. A perusal of this record quite justifies the complaints made of lack of heating. In the 31 schools of which particulars are given the minimum temperature, taken at 9 A.M. in January reached 40° F. in only one instance. In two schools it was 32° and in 15 schools it varied from 33° to 36°. It would be of interest to know whether the attendances were in any way affected at these particular schools in consequence of the badly warmed rooms.

West Wales Asylum.

At the end of the March quarter there were 676 patients in the three counties (Carmarthen, Cardigan, and Pembroke) asylum. The rate of payment for the maintenance of pauper patients has been fixed at 8*s*. 9*d*. per head weekly for the current six months.

Cardiff Water-supply.

The water-supply of Cardiff is obtained from the Brecknockshire hills, where it is impounded in two large reservoirs. Even when these works were first undertaken it was realised that it would be necessary at no very distant date to construct a third reservoir unless there came a check in the growth of the town. There seems no likelihood of that taking place, and after unsuccessful attempts at securing additional supplies of water elsewhere, including the very large quantity which has to be constantly pumped out of the Severn Tunnel springs, the city corporation decided to promote a Bill to enable it to construct the third reservoir, which will have a capacity of 1075 million gallons. A committee of the House of Commons passed the preamble of the Bill on April 23rd, so that a serious effort will now be made to proceed with the undertaking. The population of the town is now estimated at 191,500 and the daily consumption of water per head is 28 gallons. The new works will take about six years to complete, and it is anticipated that even if the present rate of increase in the population continues the additional storage provided will insure the same amount per head daily in 30 years' time. The cost of the undertaking is estimated at £272,000.

April 27th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

School Blackboards.

THE medical officer of health of Haslingden, Mr. F. J. Hindle, is also medical inspector of school children, and he has made a statement as to the injurious effect on the sight of the blackboard, that it is responsible in some degree for the defective sight of the pupils. He says that the almost constant use of the blackboard causes eyestrain, and that though his own vision is perfectly normal, he has had difficulty in deciphering things depicted on the blackboard where in other circumstances the deciphering should have been easy. He has noticed that scholars resort to various expedients to overcome the difficulties arising from the shiny surface of the board. He advises that the blackboard and white chalk should be replaced by white boards or slabs and black chalk or crayon, which, he thinks, would do away with difficulties of focus and of defective sight.

The Gore Brook Again.

It would seem that the work of the Mersey and Irwell joint committee—namely, the purification of our rivers—is still very far from completion. Salford, in spite of its endeavours, is at fault, for the dry weather flow of sewage in the borough is approximately 12,000,000 gallons a day, which is about 4,000,000 gallons a day more than the present filtration beds can deal with. So the Salford Corporation is to be asked how it proposes to deal with the increase of flow of sewage. But the Gore Brook never fails to provide a subject for discussion at the meetings of the joint committee, and to bring forth some futile efforts to prevent or minimise its offensive smells. One of the last has been to sterilise the sewage effluent during dry days in the summer months. But as the chief inspector had pointed out, "there was a distinct nuisance arising from the brook in the vicinity of Birch Park" on March 21st, not usually reckoned as a summer's day. Gorton, which has to curb the tendency of the brook to make the vilest of bad smells, says it is doing all it can and throws the blame on its advisers because they had not been sufficiently insistent in their recommendations. The present state of things is that the subcommittee of the Mersey and Irwell joint committee "recommended that the clerk be instructed to inform the Gorton urban district council of the offensive condition of the stream on the date named (March 21st), and to urge it, as the sanitary authority, to take such steps as it might find necessary in order to relieve the inhabitants of its own district and of the city of Manchester of a repetition of the nuisance during the ensuing summer." But the brook heeds not legal phraseology and is no doubt prepared to surpass its former efforts in the production of vile smells. It is a curious thing that for a long series of years this dirty ditch has defied the best efforts, as they must be supposed to be, of the joint committee, the city of Manchester, and the Gorton urban district council, and, as far as present signs go, will continue to triumph over them.

Common lodging-houses.

Some little time ago Manchester was startled by a fire at a lodging-house, where 200 or 300 people could be put up. There was some loss of life, and there seemed to be a lack of supervision over those responsible. Since then, however, action has been taken with a view of securing better safeguards against fire and panic casualties. The Local Government Board has sanctioned Manchester's adoption of Part 5 of the Public Health Acts Amendment Act of last year, and the Watch Committee will be able by the end of next month to have a system of registration and to place obligations on the owners of lodging-houses, which should improve some of them and perhaps lead to the closing of some of the less desirable.

April 27th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Needs of the Scottish Universities.

THE Treasury Committee appointed by the Chancellor of the Exchequer to inquire into the needs of the Scottish Universities and Colleges for further assistance from Imperial funds visited Glasgow last week. The Earl of Elgin (chairman), Sir Kenelm Digby, Sir Harry Reichel, Miss Haldane, Professor A. R. Forsyth, F.R.S., Professor G. Sims Woodhead, Dr. Charles Douglas, and Mr. H. Warre Cornish (secretary) met in the University Court Room and took evidence from Principal Sir Donald MacAlister, Professor Stewart, and Dr. David Murray, the representatives of the University Court. The committee afterwards inspected the new laboratories for physics, physiology, &c., the library, and the Hunterian Museum, where they were received by the respective staffs of the departments. Later in the afternoon a visit was paid to Queen Margaret College.

Medical Students and the Arts Course in the University of Glasgow.

With reference to the new regulations for the arts degree, which were under consideration last week at a meeting of the General Council of the University of Glasgow, attention was drawn to No. 2 of the regulations, which read:—

> Not more than three languages other than English, and not more than two sciences, are to be included in any curriculum.

It was pointed out that the intention of the Senate was that a double degree should not be too cheap, and the scientific [illegible] result from encouraging the medical students to take the arts degree, and it was finally agreed that the regulation should read:—

> Not more than three languages other than English, and not more than two double courses, or three single courses in the department of science, are to be included in any curriculum.

Pathologist for Royal Infirmary, Glasgow.

The directors of the Glasgow Royal Infirmary have appointed Dr. John H. Teacher pathologist to the infirmary. Dr. Teacher, amongst other appointments since graduation, has held the posts of under-curator of the anatomical and pathological departments of the Hunterian Museum, assistant pathologist at the Western Infirmary, and pathologist to the Royal Hospital for Sick Children, Glasgow.

Post-Graduate Courses at the Royal Infirmary, Glasgow.

The post-graduate courses at the Royal Infirmary for the summer session will commence on May 3rd. It will facilitate arrangements if any desirous of joining any of these classes will communicate with Dr. J. M. Thom, superintendent, who will supply any further information.

Treatment of Pulmonary Tuberculosis in Glasgow.

At a recent meeting of the Glasgow parish council a discus- [illegible] principle into action. It was decided to remit to the Relief Appeal Committee to consider applications for relief that have been made from phthisical cases, which are not legally entitled to relief, and to draw the attention of the Local Government Board to the matter. It has been stated by one of the corporation committees that to put the notification in force as desired by the parish council would put an extra 1*s.* or 1*s.* 4*d.* per £ on the rates; that the capital cost would be something like £250,000; and that at least 3000 persons would require active treatment. The parish council had no means of checking these figures, but in its opinion the spread of the disease should be checked by treating the patients in the most approved manner whenever the disease was discovered. This means that cases which are not legally entitled to relief, such as patients who at the time of the discovery of the disease are practically able-bodied, must be treated.

The Municipalisation of the Sidlaw Sanatorium.

The municipalisation of the Sidlaw Sanatorium is still the all-absorbing topic of conversation in Dundee and to all appearance the question is as far from being settled as ever. At a meeting of the council, specially convened to consider the Provisional Order to obtain powers to levy a special rate for the maintenance of Sidlaw Sanatorium, payable equally by owners and occupiers, the adoption of the Order was carried by 13 votes to 9 for the previous question. At this meeting the Lord Provost read a telegram which had been received from the Local Government Board, stating, "In view of numerous important representations against the scheme the Board cannot, without further consideration, give their statutory sanction to the proposed transfer at present." A meeting of representatives of the various public bodies opposing the scheme has also been held, when arrangements were made for taking active steps to prevent the transference of the institution to the town council becoming effective till more is known about it. Delegates from the Harbour Trust, Chamber of Commerce, Citizens' Union, House Factors' Association, and the inhabitants of Auchterhouse and district were present; and it was agreed that the Local Government Board should be asked to receive a deputation and also that a committee be appointed to consider what court proceedings should be started. On April 19th a public meeting convened by the Lord Provost was held in the Kinnaird Hall to afford an opportunity for the citizens of Dundee to express their opinion on the question. A large staff of police was on duty to preserve order. After the Lord Provost had explained the subject from the town council point of view Professor D. MacEwan moved the following resolution:—

> That it is desirable in the interests of the public health of the com- [illegible] to municipalise the [illegible] rence to the proved [illegible] influences thereby secured.

Dr. J. Mackie Whyte seconded. It was moved as an amendment that the matter be referred forthwith by the town council to the decision of the electors by means of a plebiscite. After a scene of great disorder the Lord Provost brought the proceedings to a close by leaving the chair without any decision having been arrived at. The Citizens' Union has issued a circular to the ratepayers pointing out, among other things, how the cost will cripple industries and demanding a plebiscite.

Additions to the Victoria Hospital, Dundee.

Important extensions to the Dundee Victoria Hospital are about to be made. Recently the laundry of the establishment was destroyed by fire. Plans for the making good of the damage were submitted at a meeting of the executive committee on April 23rd. These provide for the erection of a new washhouse, divided into two entirely separate compartments, one for patients and the other for the staff, each with its own washing machines. A boiler steam-engine is also to be installed, and the portion destroyed is to be renewed and a common laundry provided. The total cost is to be about £2000.

Aberdeen Sanitation: Annual Report.

The report of the sanitary inspector of Aberdeen for the year ending December last has just been issued. Favourable comment is made on the work of the two health visitors, and the suggestion is offered that it might be worth considering whether a third lady should be appointed to devote her time entirely to the question of cleanliness in the houses of the people. During the year the public health committee resolved to recommend to the council that notices should be supplied to all the principal workshops and factories in the city in regard to the danger of spitting, and the council having agreed to this recommendation there were 525 such notices issued and in every case the persons in charge of the works were willing to have the notices exhibited in their premises. There were in all 1834 cases of infectious disease removed to, or treated in, the hospitals of the city, 2151 cases supervised at home, and 11,252 visits of inquiry made in connexion with all the cases reported.

Presentation to Dr. T. A. Sellar of Aberlour.

Dr. T. A. Sellar of Aberlour has been presented with a motor-car by the inhabitants of Aberlour and district and by others residing at a distance. The movement was entered into with the utmost enthusiasm and a larger sum than that aimed at—£400—was subscribed, the additional subscriptions being returned. The car is a Mors car, 12–15, R.A.C., rating 15–9, single landaulette, and in addition Dr. Sellar was presented with a list of the subscribers, an insurance policy for one year, and a deposit receipt for £35. The chairman, in making the presentation, remarked on the size of the district served by Dr. Sellar and on the esteem in which he was held throughout it. Dr. Sellar suitably acknowledged the presentation and also that of a rug sent by Dr. W. Skinner, Ballindalloch. The meeting was characterised by great heartiness and proved the appreciation of Dr. Sellar's services to the district.

April 27th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Post-Graduate Classes at Trinity College, Dublin.

FOLLOWING the precedent of last year, arrangements have been made for both summer and autumn post-graduate courses at Trinity College, Dublin. The duration of each course will be three weeks, the hours of which will be fully occupied, the working day being from 8.30 A.M. until 6 P.M. The syllabus includes a lecture by Sir C. B. Ball, the Regius professor of surgery on Cancer of the Rectum, to which he has devoted special attention. The course in physiology has been extended and now includes lectures on the absorption and elimination of protein bodies and practical work in the laboratory for three hours each week on urinary analysis. As in former years, arrangements have been made by which a limited number of members of the class can reside in College rooms and dine on Commons for a very moderate sum.

The Anti-Tuberculosis Crusade.

The professional event of the past week in Dublin was the Anti-Tuberculosis Exhibition in the Rotunda buildings for five successive days. The arrangement formulated on the original programme was for three days only, but the appreciation of over 60,000 visitors elicited the decision of the authorities to continue the exhibition to the end of the week, and the interest of the public fully justified the movement. The impression made upon the public and upon highly qualified critics among them was most favourable. The amount of material displayed for the purpose of education was large in quantity and excellent in quality. Hardly a conceivable specimen was omitted—from the model of a byre erected in the Rotunda Gardens, in which was housed a tuberculous cow, to the microbic colonies of caseation of the various tissues and organs which were exhibited in the Pathological Section under the direction of Professor E. J. McWeeney. Good coloured pictures of the tubercle bacilli in characteristic conditions of location and grouping were prepared by Dr. C. L. Birmingham of Westport. An excellent series of charts, maps, and diagrams were on view in the Pillar Room, under the charge of the Registrar-General (Sir Robert Matheson), which supplied full and up-to-date statistical information on the distribution and mortality of tuberculosis (among other important infectious diseases) in Ireland. There were models of labourers' cottages which had been lent to the exhibition by the Local Government Board, and a complete collection of the most recent disinfecting agents, apparatus, and appliances, which had been supplied by the corporation. There was a sun-box designed by Mr. Finegan, L R.C.S.I., and chalets which were constructed by Messrs. Keenan and Sons. In the Veterinary Section were displayed some typical specimens of tuberculous disease. In the section devoted to air and ventilation Mr. G. Fletcher had brought together an interesting and instructive collection of charts and models illustrative of the value of fresh air and proper appliances for ventilation in the prevention and cure of disease. The pair of "contrast houses," which were arranged by Mrs. Rushton, formed a strikingly effective object lesson. Here were displayed two bedrooms which had been furnished at the same expense with the object of showing a diagrammatic contrast between the cleanliness, cheery lightness, and neatness of arrangement of the furniture of one, and the sombre depression and helpless untidiness suggested by the careless and ill-judged (dis-)arrangement of the corresponding items in the other apartment. In appropriate proximity to this section was displayed a protective screen which had been supplied by Messrs. Smith and Sheppard, and was made to invest completely the bed of a tuberculous patient and thereby to act as a preventive against contagion. The Domestic Science Section, which was under the charge of Miss Fletcher, and the Milk Section, which was under the control of Miss McNeill and Dr. J. Lumsden, were also amongst the most successful attractions of the exhibition. In the Pillar Room during the exhibition the large central table was loaded with pamphlets and leaflets for free distribution.

The Medical Officer of Health of Belfast.

At a meeting of the public health committee of the city of Belfast held on April 22nd the following communication was read from the secretary to the Local Government Board for Ireland :—

> With reference to your letter of the 26th ult. relative to the resolution of the Belfast corporation increasing the salary of the medical officer of health from £600 to £800 by four annual increments of £50, I am directed by the Local Government Board to remind the corporation that after Dr. Whitaker's resignation in 1906 the Board strongly urged the corporation to fix a salary which would induce candidates to come forward possessing high qualifications and extensive practical experience in the sanitary administration of a large city. Notwithstanding the Board's representations and the recommendations of the Public Health Committee, the corporation adhered to their decision to fix £600 a year as the remuneration of the medical superintendent officer of health, and consequently appointed a gentleman who had only within the preceding year obtained the prescribed diploma in public health, and had not the advantage of previous training in sanitary administration. The Board cannot lose sight of the fact that the corporation, after full deliberation, less than three years ago, assigned £600 as the remuneration for the work, and that Dr. Bailie accepted office on these terms, and, having regard to their usual practice of declining to consider proposals to increase salaries until five years have elapsed after the appointment, on the ground that the fixing of a low initial salary would tend to limit competition and discourage eligible candidates, they feel unable to concur in the present proposal of the corporation.

A resolution was passed by the committee protesting against the action of the Local Government Board.

Scarlet Fever in Lurgan.

A widespread epidemic of scarlet fever has broken out in the Blough district of Lurgan. The type so far is mild, but as reported on April 19th to the urban council 46 cases have occurred, with two fatalities. Its spread was attributed by Dr. S. Agnew, medical officer of health, to the giving out of home work from one or two factories. In some of the homes disinfected they found bundles of handkerchiefs, and as the children went to and from the offices daily with such bundles every facility was given for spreading the disease. There is also a suspicion that the epidemic may be a milk one.

Royal University of Ireland.

Dr. John Campbell of Belfast has been re-elected a member of the Senate (a representative of Convocation) of the Royal University of Ireland. He had 272 votes to 94 polled for Dr. E. Magennis of Dublin.

April 27th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Getting up After Laparotomy and Labour.

AT a recent meeting of the Society of Medicine M. Lance discussed this question, which at the present time is a matter of debate on all sides. For the last dozen years surgeons, both in Germany and America, have advised that cases of laparotomy should be got up early. M. Lance undertook an inquiry as to the actual practice of French surgeons, both in Paris and the provinces, and reported to the meeting the results of his inquiry bearing on the indications both for and against this method. It would seem that in the majority of cases the ordinary stay in bed can be considerably shortened with profit to the patient, given certain conditions and modifications in the method of operating and of dressing. M. Theuveny considered that as regards the getting up of a patient after labour, the condition of involution of the uterus and the lochial discharge must be taken into consideration. No absolute rule can be laid down, for patients who had had many children, patients who had been delivered of twins, patients who were suffering from infection and who had had a very tedious labour followed by uterine subinvolution, ought to be kept in bed for some time, while, on the other hand, the patient whose uterus had sunk behind the pubes and whose lochial flow had stopped within nine days could then get up without danger. Getting up on the third or fourth day after labour was in M. Theuveny's view very imprudent. M. Cazin said that no definite rule could be laid down as to the getting up of a laparotomy patient; in the case of a patient who had undergone an operation for fibromyoma one could not be too careful. M. Dartigues said that M. Lance had been quite right in bringing up the question before the society, for it was one which was of interest at the same time to physicians, surgeons, and accoucheurs.

Some Cases of Œsophagoscopy and of Tracheoscopy.

At a meeting of the Society of Œsophagoscopy and Tracheoscopy, held on April 8th, M. Guisez showed sundry [illegible] d rendered great services [illegible] point of view. One case [illegible] apparently arising from [illegible] near the cardiac end of [illegible] ent gave reason for [illegible] ple ulcer which had [illegible] is idea and allowed [illegible] of the œsophagus was at the normal. In another case a dilatation of the aorta was diagnosed both by tracheoscopy and œsophagoscopy. This case was remarkable, for it was the first in which endoscopy afforded a diagnosis, the clinical signs being negative. Two other cases were those of foreign bodies in the œsophagus which were removed by the aid of œsophagoscopy, one being some false teeth and the other a piece of chicken-bone. In this last a portion of the wall of the œsophagus had sloughed, but the patient recovered without any bad symptoms.

The Treatment of Tuberculosis by Tuberculin.

At a recent meeting of the Academy of Sciences Professor Bouchard read, on behalf of Dr. Mantoux of Cannes, a note on the treatment of tuberculosis by tuberculin. This drug has given good results in a number of cases, but its employment is one of extreme delicacy which has militated against the more general use of the method. Dr. Mantoux injects the tuberculin, not under the skin, as has been the custom up to now, but into the thickness of the skin. It there produces a wheal (*tache*), the appearance and dimensions of which are, [illegible] physician in the administration [illegible] way can be graduated, [illegible] e temperament of the *patient and can be increased in proportion to his resistance* without fear of any untoward circumstance.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The German Balneological Association.

THE German Balneological Association recently held its annual meeting in Berlin, Professor Brieger being in the chair.

Dr. Schmidt of Halle read a paper on Diarrhœa, in which he said that the principal feature of this condition was not the increase of peristaltic movement, but a putrid discharge from the intestinal mucosa. Concerning the therapeutic measures apart from a suitable diet, opiates, [illegible] condition. The best remedy was peroxide of hydrogen, which even in small doses was bactericidal.

Professor Kutner of Berlin read a paper on Dietetic "Cures," especially on over- and under-feeding. In adults, overfeeding was prescribed in anæmia, nervous diseases, in convalescence, and in commencing tuberculosis, but good results were obtained only when the digestive organs were healthy. The individual patient required an individual cure, and it was of importance to ascertain his tolerance for fat and carbohydrates. Some patients felt better with absolute rest in bed; other patients required some exercise. The routine prescription of the Weir-Mitchell method was therefore not satisfactory and must be avoided lest it should produce obesity. Still more precaution was required in underfeeding, and a too rapid application of this method was injurious because it might produce nephritis. Muscular work should always be prescribed. Dr. Pariser of Homburg said that constitutional obesity must be differentiated from obesity produced by overfeeding. Constitutional obesity was thyreogenic, and hypertrophy of the thyroid gland was always present. The diagnosis of constitutional obesity should not be made before it had been proved that the condition was not influenced by dietetic measures; in these cases the administration of thyroid preparations was advisable, but not in cases of overfeeding.

Dr. Determann of St. Blasien had made experiments on the Viscosity of the Blood in vegetarians and non-vegetarians, of each category in five cases. He found that the viscosity was greater in vegetarians; the principal cause of the viscosity was the globulin, whilst the sugar and the salts were without importance. He then administered in different periods a food containing much and little albumin, much and little fat respectively, and found that the food had only a small influence on the viscosity, but that the latter *depended on the quantity of hæmoglobin.*

Dr. Gottschalk of Berlin spoke on Balneotherapy and Menstruation. He pointed out that drinking "cures" might be continued during menstruation, although they might sometimes increase the blood pressure; bathing "cures," however, should always be interrupted, first because the water might contain germs which might eventually enter into the vagina and find there a good medium for growth in the discharged blood. The bactericidal action of the blood in the vagina was, moreover, decreased and the aperture of the cervix opened, so that an infection might easily happen. Mud baths should never be administered for hæmorrhage due to myomata. During menstruation the normal blood *pressure decreased* and it should not be *artificially increased* by bathing.

Dr. Schreiber of Konigsberger read a paper on Accidental Albuminuria. He had observed that palpation of the abdomen caused a temporary albuminuria in a person with atonic abdominal walls. He found the same symptom in many other people. Probably it was caused by irregularity of the renal circulation. In the discussion, Professor Brieger observed that more caution should be taken in palpating the abdomen. He had found by experiments on animals that pressure on the aorta not only caused albuminuria but also degeneration of the spinal cord. Dr. Pariser was of opinion that the albuminuria might be due to arteriosclerosis. Massage of the abdomen, which was the strongest form of palpation, had, in his numerous cases, never caused albuminuria.

Dr. Engelmann of Kreuznach discussed the Radio-active Substances in the Kreuznach springs. They were present in, and were obtained by, chemical proceedings from "sinter"—i e., residues—of which every year large quantities were produced. The radio-active emanations had been used in rheumatism, neuralgia, and sciatica, and lately in the Cancer Institute of Heidelberg by Professor von Czerny. In the discussion, Dr. Fürstenberg of Berlin said that the emanations did not penetrate through the intact skin, and that the effect of radio-active baths was therefore rather small. Radio-active waters were, according to him, most efficacious when given orally or by inhalation.

Professor Strauss of Berlin discussed the question of the Influence of Drinking Cures on the Blood Pressure. He had [illegible] in numerous cases that the [illegible] lood pressure. [illegible] only in very [illegible] r, not greater than that produced, for instance, by mastication. The administration of fluid was thus not at all harmful. In diseases of the kidney, where the increase of blood pressure was caused by the retention of nitrogenous productions of the metabolism, a drinking treatment might eventually have a curative effect by removing those toxic productions. It was not yet *ascertained whether the blood pressure decreased* by the administration of purgative waters.

Dr. Schuster of Aix-la-Chapelle reported the results obtained in Syphilis by the combination of the Aix-la-Chapelle sulphur springs with the administration of mercury. It had been alleged that this combination might eventually produce sulphate of mercury, which was inert. This opinion was, however, eironeous. Dr. Schuster succeeded in proving by quantitative analysis that during a "combined" cure of from five to six weeks the daily discharge of mercury was 6–7 milligrammes. After seven weeks it was 3–3·5 milligrammes, and after four months not more than 2 milligrammes were present in the urine. Dr. Schuster concluded that the combined cure was efficacious because the mercury was as easily absorbed as discharged, because the mercury was retained within the circulation for an adequate time, and because the Aix-la-Chapelle waters, owing to their amount of sulphur and of chloride of sodium, had themselves a curative effect on syphilis.

Dr. Fürstenberg read a paper on the Hydropathic Treatment of Neurasthenia. He said that the essential thing was to administer exact doses, and that therefore a thorough knowledge of hydropathic technique was necessary. It was a common fault for inexperienced medical men to prescribe too strong or too many applications. For proper treatment care must be taken to ascertain whether the patient offered more symptoms of irritation or of depression. In both cases the "cure" should be begun with local applications which were of very mild action. Afterwards general bathing, sponge baths, or half baths might be prescribed. In cases of nervous irritation packing or protracted "indiffeient" baths were advisable. In sanatoriums other means such as fan-douches of changing temperature might be applied. Dr. Fürstenberg then gave prescriptions for the treatment of the local symptoms of neurasthenia, such as insomnia, headache, sexual irritation, &c., but pointed out that every case required individual treatment.

Dr. Frankenhausen of Berlin discussed the Training of Students in Balneology in the German Universities. He regretted to-day that the German universities had hitherto somewhat neglected the training of students in this branch of medicine, the result being that the overwhelming majority of young medical men begin practice without having any knowledge of health resorts and watering-places. This was a great drawback, as nowadays a medical man might be compelled to prescribe balneological or climatological treatment. Dr. Frankenhäusen made some proposals for improving this undesirable state of things; he recommended that balneology should be a subject of examination in the State examination, that balneological institutes should be established at the universities, and that excursions of the students should be arranged to the most important watering-places under the guidance of the clinical teachers.

Other papers read before this Congress concerned the Blood Pressure in Arterio-sclerosis by Dr. Kisch of Marienbad, Health Resorts on the Seaside by Dr. Haeberlin of Wyk, Hygiene of Health Resorts by Dr. Sarason of Berlin, and Balneotherapy in Childhood by Dr. Hirsch of Kudowa.

April 24th.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

Country Places and Infectious Diseases.

As the time is now fast approaching when the higher and middle classes of the city's population are beginning to remove to country places on the upper part of the Bosphorus or on the so-called Prince's Islands in the Ismid Gulf of the Sea of Marmora, the serious attention of the medical authorities and the public is drawn to the fact that a great many of these places are very unsatisfactory from a sanitary and hygienic point of view. Some medical men who seem to know the prevailing conditions and circumstances, and who have given the matter proper consideration and made careful investigations, maintain that a good number of people who leave the narrow, dirty, and dusty streets of the city in order to enjoy the bright sunshine and the pure air of country places frequently return in a worse state of health than that they have been in previously to their removal. The reasons assigned to account for this regrettable fact are manifold. To begin with, almost all the houses on the Upper Bosphorus and the Marmora Sea are built of wood without any consideration as to the comfort or well-being of the people. Besides, the streets there are in many places so narrow that the balconies of opposite dwellings almost touch one another. Whereas in the city wherever a case of acute or chronic infectious or contagious disease is recognised the dwelling and clothing and furniture are disinfected under more or less efficient medical supervision, this disinfection is almost never carried out in country places, which have no organised medical service. It is said by a medical authority that on the Prince's Islands there is scarcely a house that has not been inhabited by a phthisical patient. In spite of that, these houses have never received a medical visitor for purposes of disinfection. The hope is expressed that the medical authorities will take the necessary measures to remedy this state of affairs, which is so dangerous to the public health.

Cerebro-spinal Meningitis.

Dr. J. B. Violi, a recognised authority here on children's diseases, thinks that the cerebro-spinal meningitis which has been epidemic of late in Northern Europe, in Switzerland, and in Italy is beginning to spread also in the Turkish metropolis. For many years past there have been only sporadic cases of this malady here and there, all strictly localised. At the end of February, 1907—i.e., soon after the European epidemic—the disease began to spread on the banks of the Bosphorus and the Golden Horn in an alarming manner. Dr. Violi does not think, however, that cerebro-spinal meningitis has come to Constantinople from Western Europe. He expresses the view that the disease originated in the Turkish metropolis and that the conditions are much more favourable to it now than they were in former years. In 1907 it reached its maximum intensity during the months of April, May, and June; it diminished in July and August, and disappeared in the autumn. In 1908 it reappeared at the end of February with the same progression and decline as in the previous year, and with the sole difference that fewer adult people were affected by it. This year it began again to manifest itself in the same month of February and is now seen in an epidemic form among the children. Dr. Violi advises parents not to be over anxious, as the present disorder, he thinks, is not of a severe type, is not likely to propagate itself extensively, and does not resemble the epidemics in western and southern Europe. The mortality figures as given by the Conseil de Santé show that in 1907 22 persons died from cerebro-spinal meningitis. In 1908, of the 250 cases 25 succumbed. These figures do not include the numbers of patients who died from tuberculous meningitis. Of the various remedies used Dr. Violi found that the injections of the anti-meningococcic serum of Merck (in repeated doses of 10 cubic centimetres) gave the most satisfactory results. The injections of collargol and Rodmann's methods did not come up to expectation. Five patients treated with Merck's serum rapidly recovered.

The Political Disturbances.

All sorts of rumours are abroad in the city and everybody is in a state of great anxiety and apprehension. It is felt that something decisive will happen soon and fear is felt that renewed bloodshed is unavoidable. The opinion is expressed on all sides that so long as the present Sultan, Abdul Hamid, remains there will be no end to the trouble. But the young constitutional party know two things well—the one is that a religious outburst of a magnitude that cannot be gauged might follow the time-honoured method of dealing in the East with a fallen sovereign, while Europe expects the party of regeneration not to look back for their models to blood-stained pages of history.

April 23rd.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Plague.

PLAGUE has not failed to reappear in Sydney as usual in the autumn and the present outlook is disquieting. The first case registered was that of a seaman on the French steamer *St. Louis* which trades between Sydney and Noumea. Almost simultaneously an employee in a city flour mill was found to be suffering from the same disease. A day later the proprietor of this establishment and his brother were removed to the Coast Hospital and both died [illegible] strict inquiry into the conduct of the officials responsible for the inspection of these premises. Another case is also registered from the steamer *St. Louis.* It was supposed that Sydney was originally infected from Noumea, but the evidence each year goes to show that the infection is slowly spreading from the wharves to the inner suburbs. Dr. T. W. Sinclair, the acting city health officer, admits that some of the foreshore is in a very bad state. Plague is also reported from Banbury, a small port in the North of Western Australia, where an outbreak occurred in the crew of a steamer from Singapore.

The Medical Inspection of School Children.

The Government of South Australia has appointed Dr. R. S. Rogers as medical inspector of school children and will formulate a scheme of its own. At the Premiers' conference of 1908 action was delayed pending an agreement for a scheme among the various States on uniform lines. Nothing has been done and South Australia declines to wait any longer. School inspection has been carried out in Tasmania and New South Wales for the past two years, but no general plan is followed.

Presentation to a Surgeon.

Mr. G. A. Syme, M.S. Melb., F.R.C.S. Eng., who is leaving for a holiday trip to Europe, was entertained at dinner by the members of the Victorian Police Force on March 19th. Mr. Syme has held the position of surgeon to the Victorian police for many years and has earned the esteem of all ranks. The presentation consisted of an illuminated address and a smoker's companion, while Mrs. Syme received a handsomely fitted travelling case. Mr. Syme has also been entertained by the medical profession at a farewell dinner.

A Proposed New Clinical School.

[illegible] f Medicine in [illegible] St. Vincent's [illegible] is the most recently built hospital in Melbourne and is managed by a nursing sisterhood of the Roman Catholic Church. At present about 120 patients are accommodated and the appointments are admirable as far as ward and theatre equipment are concerned. The Faculty has appointed a subcommittee to report on the matter and appears sympathetic, although the facilities for pathological investigation will have to be improved before the request can be entertained. Hitherto the Melbourne Hospital has been practically the only clinical school for general teaching available for University students. The Alfred Hospital has sufficient facilities and is recognised, but is too far away to be of much service. St. Vincent's is as near the University as the Melbourne Hospital and has a very large out-patient department with all the usual special subdivisions.

Fever Hospital Accommodation in Melbourne.

Attention has lately been drawn in the public press to the inadequate hospital accommodation for infectious diseases in Melb[illegible] such [illegible] fever [illegible] institution have been characterised as faulty. It possesses only two wards and hitherto has been without an observation block, though this is being added. It is not a charitable [illegible] per diem, which, moreover, must be guaranteed. The Government contributes half the upkeep but has no representation in the management. There is ward accommodation for about 60 patients. Recently a mild epidemic of scarlet fever has appeared in Melbourne and the accommodation of the hospital has been greatly overtaxed, a number of patients having to be treated in tents erected in the hospital grounds.

A Useful Career.

Mr. T. H. Lovegrove, chairman of the Board of Public Health and Chief Government Medical Officer for Western Australia, will shortly retire owing to advancing years. Mr. Lovegrove arrived in Western Australia in the very early days and has been continuously in the Government service ever since. He has done a vast amount of valuable organisation in public health work and hospital administration. He introduced female nurses into the Perth Hospital against a fierce storm of press and public opposition. He has always been a highly popular public servant and possessed the confidence of every Government throughout the many changes of administration that Western Australia has experienced in the last 30 or 40 years.

Care of Inebriates.

The Government of Victoria some time ago opened an inebriate retreat at Lara, near Melbourne, and objection has recently been made by a prominent temperance advocate that admission appeared only to be for a favoured few. Replying to these statements Mr. Ernest Jones, Inspector-General of Insane, insists that the retreat is only for voluntary patients and is in no sense custodial. Of 97 patients admitted between July, 1907, and December, 1908, 30 were received without payment, 42 paid £1 per week or less, and only 14 had paid full cost of maintenance. Admission therefore does not depend on ability to pay fees. "Our endeavour throughout," says Mr. Jones, "has been to obtain and cure those patients who are deserving of assistance and treatment and who are likely to benefit by their stay at Lara. Practically only those who make voluntary application are likely to benefit by their stay in such an institution; those who are sent there compulsorily are rarely likely to do any good and for such characters a farm colony is probably the only solution of the difficulty. But such a colony must also be custodial; it would be impossible to give to such patients the liberty which is allowed at Lara. There is accommodation for 50 male patients and we have only about 20. There are immense possibilities for doing excellent work at the institution and, I take it, it is only with the coöperation of the temperance societies that it can be made a success. We have no authority to go out and collect patients but we are always ready to receive and care for those brought to us, provided they are suitable cases for treatment in a remedial institution as opposed to a custodial one."

March 23rd.

Obituary.

SIMEON SNELL, F.R.C.S. EDIN., D.SC. SHEFFIELD,

PRESIDENT OF THE BRITISH MEDICAL ASSOCIATION; OPHTHALMIC SURGEON TO THE SHEFFIELD ROYAL INFIRMARY; PROFESSOR OF OPHTHALMOLOGY IN THE UNIVERSITY OF SHEFFIELD.

Simeon Snell, who died on April 17th during his term of office as President of the British Medical Association, was, as many of our readers will remember, in somewhat failing health during the meeting of the Association which was held at Sheffield last year, and in fact was unable to undertake the whole of his arduous duties. After the meeting he took a long holiday and on his return to work found it necessary to give up many of his numerous engagements. Some eight or nine weeks ago, however, he had to take to his bed, and although he improved about a week before his death the improvement was only temporary and he died, apparently from heart failure, while asleep, the primary cause of death being arterio-sclerosis.

Mr. Snell was born in 1851, the son of a medical man. He received his medical education at Leeds, Guy's Hospital, and the Royal London Ophthalmic Hospital, Moorfields. He qualified M.R.C.S. Eng. in 1872 and L R C.P. Lond. in the following year. In 1892 he became a Fellow of the Royal College of Surgeons of Edinburgh. He settled in Sheffield in 1874, and in 1876 was appointed ophthalmic surgeon to the Sheffield Royal Infirmary, a post which he held to the day of his death. We have received the following interesting particulars from Mr. T. Pridgin Teale upon Simeon Snell's career at this juncture: "Somewhere about the year 1869 a father brought three sons to enter them for the surgical practice at the Leeds Infirmary. The eldest, Enoch, is in practice at Nottingham. The second, John, died a short time ago at Gargrave in Yorkshire. The third, Simeon, is the one whose recent death in the height of his fame we are now deploring. About the time of his obtaining his diploma he acted as my private clinical assistant, and thus his interest and attention were directed towards ophthalmic science, an interest which was confirmed and intensified by his subsequent attendance at Moorfields and his association with Sir William Bowman. When the time arrived for his settling down in practice he became a partner with a family practitioner in Sheffield, being attracted to the partnership by the fact that the gentleman had a considerable ophthalmic *clientèle* and was at the time the chief ophthalmic surgeon in Sheffield. This gave him his opportunity, fresh as he was from Moorfields and inspired by all the latest developments of ophthalmic science. How from such a basis he rapidly acquired a leading position in the town, and eventually in the Sheffield Infirmary, everyone knows. Clear-headed, accurate, and enthusiastic, he was keenly alive to all advances and improvements in ophthalmology, whether in this country or in foreign lands." Snell at once began to take a deep interest in the Sheffield Medical School and was an energetic advocate of the University of Sheffield scheme. When this ideal was realised and the Sheffield Medical School became the Medical Faculty of the University, Snell was elected Professor of Ophthalmology and was also given a seat on the Council. His studies in ophthalmology naturally enough chiefly related to those diseases and affections of the eye which are brought about by industrial conditions, and he wrote the article on Eye Diseases and Eye Accidents in Relation to Industrial Occupations which formed part of the treatise on "Dangerous Trades" which was edited and published by Dr. (now Sir) Thomas Oliver in 1902.

In 1908 Snell received the well-deserved honour of election as President of the British Medical Association when it met at Sheffield. In his admirable Presidential Address he dealt with Sheffield as having been the "cradle of the study of industrial diseases." After giving a short account of those Sheffield medical men who had studied and reported upon various industrial diseases, especially those incident to grinders, he passed on to consider those industrial diseases which came before him more prominently in his capacity of ophthalmic surgeon. The class of disease which pre-eminently affects grinders is, of course, pulmonary disease, but eye injuries from dust and pieces of steel are also common. Many of our readers will remember the pictures given of Sheffield trades and of the workman who had a reputation among his fellows for removing foreign bodies from the eye, which Charles Reade gives in his novel, "Put Yourself in His Place." Snell in his address divided the affections and diseases of the eye which he had an opportunity of studying, under four heads: (1) diseases due to occupations involving prolonged use or excessive strain of the eyes and their muscles, such as nystagmus in coal miners and in other employments; (2) those due to occupations which involve the use of certain poisonous substances, such as di-nitro-benzol, used in making explosives, and of bisulphide of carbon, and others; (3) a consideration of the effects on the eye of occupations involving exposure to excessive light or heat or both, such as burnishers, steel smelters, electric welders, bottle makers, &c.; and (4) injuries or accidents amongst grinders, iron and steel workers, coal miners, &c.[1] The remainder of his address was mainly taken up with an account of miners' nystagmus, in which he showed how easily this complaint might become a source of danger. The duty of ascertaining whether or no the air in a mine is safe—i.e., free from explosive gases, depends upon men called deputies who go about the mine and estimate the amount of gas in the air. This is done by turning down the flame of the safety lamp until it practically ceases to be luminous, when if gas is present the flame is capped by a pale blue flame above the lamp flame. Snell made a series of exhaustive tests and found that miners afflicted with nystagmus could not see this cap until it attained a size which showed that a dangerous amount of gas was present. The bearing of this upon the safety of the mine and the men therein is obvious. At this meeting the Council of the British Medical Association conferred the Middlemore medal upon their President for his distinguished services to ophthalmology, and last year also the University of Sheffield gave him the degree of D.Sc. In addition to carrying on a large private practice, arduous hospital work, and teaching, Snell found time to write a good many books upon the diseases of, and accidents to, the eye, although he contributed but little to the medical journals. Outside his purely professional life he took great interest in education, and he served for many years as honorary secretary of the Sheffield Literary and Philosophical Society. In 1893 his secretaryship was interrupted by his being elected President, but at the end of his year of office he resumed his former post. In 1897 he was made a justice of the peace. The funeral took place on April 21st at Fulwood Cemetery.

Mr. Sinclair White, senior surgeon to the Sheffield Royal Infirmary, writes to us as follows: "The death of our colleague is a great loss to the infirmary—how great only those who were privileged to work with him can fully appreciate. For 32 years he gave lovingly and unsparingly of his valuable time and skill to the suffering poor who sought his aid, and the very commodious waiting-hall of the out-patient department was often filled to overflowing by his patients. He was a man of extraordinary energy, great courage, and transparent honesty of purpose. Anything he undertook was sure to succeed, if success was possible. An exceedingly busy man, he got through an amount of work which to many would appear incredible. This was achieved by virtue of the faculty he possessed of doing most things outright and at once. He was a man of many parts and contrived to stamp his individuality on everything he did. His ceaseless energy found outlets beyond his professional work, and there are very few Sheffield institutions that have not at one time or another benefited by his help. As an ophthalmic surgeon he took high rank. His numerous and valuable contributions to the literature of his subject gained for him a world-wide reputation. As an operator he had few equals. He appeared instinctively to know the right thing to do and did it with a celerity and delicacy of touch which stamped him as an artist in his specialty. The crowning honour of a strenuous life came less than a year ago when, on the unanimous recommendation of his local *confrères*, he was elected President of the British Medical Association. Although the shadow of his approaching fatal illness was upon him, he threw himself with his accustomed energy into the work of organising the Sheffield meeting, and it was very largely owing to his personality and the loyal coöperation he was able to inspire that the Sheffield Congress proved to be one of the most successful in the history of the Association. The rank and file of the profession found in him an ever-ready champion of their rights and will greatly miss his masterful leadership, while his immediate colleagues mourn the premature removal from their midst of one who embodied staunch loyalty, a kindly spirit, and much wisdom."

WILLIAM GABRIEL ROCKWOOD, M.D. MADRAS, M.R.C.P. LOND., M.R.C.S. ENG.

THE death is announced, on March 24th, of Dr. W. G. Rockwood, the leading Ceylonese surgeon and a practitioner well known to medical men in this country. Many of our readers will remember him at the meeting of the British Medical Association in Manchester in 1902, which he attended as the delegate of the Ceylon branch of the Association. Dr. Rockwood was born in Jaffna in the north of Ceylon in 1843 and was educated at the Vembadi Boys' School, at the Presidency College at Madras, and at the Madras Medical College. He received the Licence of this College in Medicine and Surgery in 1861 and returned to Ceylon, when he entered the Government medical service, being stationed first at Puttalarv and later at Jaffna, Hambautola, and Gampola. In 1867 he was transferred to Colombo as surgeon in charge of the General Hospital there, a post he held until 1883, and was appointed lecturer on surgery, diseases of the eye, and midwifery. In 1872 he graduated M.D. of the University of Madras. In 1884 he came to England to obtain a British qualification and in 1885 became M.R.C.P. Lond. and M.R.C.S. Eng. He then returned to Ceylon and continued his practice, which was largely of a surgical nature. In 1898 he retired from the Government service under the age-limit and that same year was appointed Tamil Member of the Ceylon Legislative Council. In this capacity he attended the coronation in 1902. At the expiration of his term of office he was reappointed for another five years but failing health compelled his retirement in 1906. The funeral took place on March 29th at the General Cemetery, Colombo, the officiant being the Rev. William Henly of St. Michael and All Angels, Polwatte. There was a very large attendance composed of members of nearly every community in the island.

---

[1] THE LANCET, August 1st, 1908, p. 289.

CHARLES BELL TAYLOR, M.D. EDIN., F.R.C.S. EDIN., M.R C S. ENG.

Charles Bell Taylor, who died on April 13th in his eightieth year, was one of the best known ophthalmic surgeons in the Midlands. He was the son of a veterinary surgeon and received his medical education at the University of Edinburgh and in Paris. In 1852 he took the diploma of Member of the Royal College of Surgeons of England, and in 1867 that of Fellow of the Royal College of Surgeons of Edinburgh, having previously graduated as M.D. in 1854. He was for many years surgeon to the Nottingham and Midland Eye Infirmary, and had besides a very extensive private practice The wide experience which he thereby gained he put to great use on behalf of his fellows in the admirable clinical lectures which he used to deliver at the Nottingham Eye Infirmary. Many of these appeared in our columns between the years 1884 to 1895, one of the most valuable being that which appeared in our first volume for 1887 entitled "Eye Diseases in General Practice." These lectures were models of a simple, clear, and incisive style, and they were further illustrated with careful drawings made and engraved upon wood, for Dr. Taylor never would have a process block of any kind. His manual dexterity was very great; he preferred to operate for cataract without the use of anæsthetics, and till shortly before his death he was in full swing of ophthalmic practice. He was a man of very strong opinions, many of which ran counter to accepted medical tenets, but in all his differences of opinion he showed himself a perfectly fair as well as a very able adversary. By his death the profession loses a skilful exponent of his branch of surgery and a thoroughly able man.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Plimeus S. Conner, formerly professor of surgery in the Medical College of Ohio, Cincinnati.—Dr. Rudolf Haug, extraordinary professor of otology in the University of Munich—Dr. Robert Reyburn, professor of hygiene in the Howard University, Washington.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery—H. A. Hancock (Section I.), London Hospital
Medicine—B. A. Keats (Sections I. and II.), St. Bartholomew's Hospital.
Forensic Medicine—B. A Keats, St. Bartholomew's Hospital; and S. H. Scott, London Hospital
Midwifery—L Ettinger, C. P. and S., New York, J. A. Koch, Amsterdam, R. Lamort, University of France, B. W Loewenberg, Berlin; S H. Scott, London Hospital, and T. A. P. Tyrrell, St. Mary's Hospital.

UNIVERSITY OF LIVERPOOL.—At examinations for the degrees of Bachelor of Medicine and Master of Surgery the following were successful:—

Anatomy and Physiology—H el Arculli, F Dallimore, T. B Evans, H. V. Forster, Elsie C. Hanson, H. W. Jones, R Kennon, R. H Knowles, T. H. Martin, H Nield, A. L. Oluwole, W H. Parry, H. Pierce, J. P. Rafter, H. G. Roberts, A. Seddon, and S. N. Wright.
Materia Medica.—G. S A. Bishop, F. G. F. Browne, D. H. Clarke, P. le F. Nortje, and T. O. Williams

FINAL EXAMINATION.

Part A.—A. Adams and T. O Clarke
Part B.—J. A. Donnellan, A. A. Rees, S. P. Sykes, and S. V. Tinsley.

Diplomas in Public Health have been conferred upon the following:—

C S Brewer, H. M. Cargin, Katharine R. Drinkwater, D. T. J. Glover, C. O Stallybrass, and J. Teare.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the recent examinations of the Royal Colleges of Physicians and Surgeons of Edinburgh and Faculty of Physicians and Surgeons of Glasgow for the triple qualification L R.C.P.E, L.R C S.E., and L F.P.S.G., the following candidates passed their respective examinations:—

F[illegible], A. M. Robertson, W. [illegible]
Se[illegible] Herick, C. S Owen, A. L. [illegible], F. F. Keravalla, H. R. Macnab, C. Hunter, and A Caruana
Third Professional Examination.—H F. Williams, J. Blackburn, P. Walsh, C A. O Driscoll, J. W. Robertson, D. B. Gazdar, W. Browne, E. D. Shroff, F P. Quirk, N. B. Mehta, W. M Thomson, R C. Fuller, and S N S Aizangar.
Final Examination.—D. G. Lindsay, N. D. Mehta, J. M'Call, V. G. Gokhale, H. E. Swan, and I. Pulteney.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Piper has been recognised as *privat-docent* of Physiology.—*Bologna:* Dr. Guido Piccinini has been recognised as *privat-docent* of Materia Medica and Experimental Pharmacology.—*Florence.* Dr. Ambrogio Mori has been recognised as *privat-docent* of Pædiatry.—*Gottingen:* The title of Professor has been granted to Dr. Alfred Putter, *privat-docent* of Physiology, and to Dr. Heinrich Vogt, of the Senckenberg Institute, Frankfort.—*Naples:* Dr. Emilio Ugo Fittipaldi has been recognised as *privat-docent* of Medical Chemistry.—*New York (College of Physicians and Surgeons):* Dr. William G. MacCallum, professor in the Johns Hopkins University, Baltimore, has been appointed to the chair of Pathological Anatomy in succession to Dr. T. Mitchell Pruden, resigned.—*Padua:* Dr. Carlo Molon has been recognised as *privat-docent* of Medical Pathology; Dr. Carlo Bestin as *privat-docent* of Neurology and Psychiatry; and Dr. Ugo Dall' Acqua as *privat-docent* of Operative Medicine.—*Palermo:* Dr. Gaetano Lodato of Sienna has been appointed Extraordinary Professor [illegible]: Dr. Giunio Salvi of Sassari has [illegible] Professor of Anatomy.—*Rome:* [illegible] recognised as *privat-docent* of Laryngology and Rhinology.—*Turin:* Dr. Giovanni Marzo has been recognised as *privat-docent* of Psychiatry and Dr. Rodolfo Bressanin as *privat-docent* of Ophthalmology.—*Vienna:* Dr. Samuel Jellinek has been recognised as *privat-docent* of Medicine.

MEDICAL SICKNESS AND ACCIDENT SOCIETY.—The usual monthly meeting of the executive committee of this society was held on April 16th, Dr. F. de Havilland Hall being in the chair. Mr. J. Brindley James, Dr. F. J. Allan, Dr. W. G. Dickinson, Mr. William Thomas, Dr. F. C. Martley, Mr. H. P. Symonds (Oxford), Dr. W. A. Dingle, Dr. W. Knowsley Sibley, Dr. Frederick S. Palmer, Mr. Edward Bartlett, Dr. M. Greenwood, and Dr. J. B. Ball were also present. The records of the spring are, on the whole, satisfactory. As usual at this time of the year the number of sickness claims has been large, but for the most part they have been of short duration, and the total amount disbursed in respect of them is less than in the corresponding period of last year. The committee examined the drafts of the quinquennial valuation and annual report. The business of last year was exceptionally good, and the 12 months' working has for its result a substantial increase both in the number of members and in the financial reserves of the society. The quinquennial valuation report will also be found to be good, and the committee will be enabled to recommend to the members a continuance of the payment of the liberal scale of bonus arranged for in 1904. Prospectuses and all further particulars may be obtained on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33, Chancery-lane, London, W.C.

MIDWIVES ACT COMMITTEE.—The tenth meeting of the Departmental Committee appointed by the Lord President of the Council to consider the working of the Midwives Act was held at the Privy Council Office on April 28th, Mr. Almeric W. FitzRoy, the clerk of the Council, presiding. The following witnesses attended and gave evidence:—Miss K. Stephenson, honorary secretary of the Wiltshire County Nursing Association; Miss Lilian Trendell, certified midwife, lately inspector of midwives for the county council and county superintendent of the county Nursing Association in Herefordshire; Mrs. Elizabeth Miles, certified midwife, Hertford; Miss Alice Gregory, certified midwife, honorary secretary and district superintendent of the Home for Mothers and Babies and Training School for

William Collins differed from his colleagues in regard to the authority which should maintain the ambulance service. They *proposed to confer the duty* on the Metropolitan Asylums Board, whilst he was anxious that the London County Council should undertake the work.

HOUSE OF COMMONS.

Wednesday, April 21st.

The Sale of Disinfectants.

Mr. Rees asked the President of the Local Government Board whether, in view of the promise made by him in June, 1907, and the statement of Professor Hewlett in the recent Milroy lectures before the Royal College of Physicians of London to the effect that during the years 1905, 1906, and 1907 28,000 gallons, 37,000 gallons, and 66,000 gallons of liquid were sold as disinfectant under the Privy Council Order of July 31st, 19[illegible] colourmen were prohibited from sellin[illegible] han 3 per cent. of carbolic acid, the [illegible] authorities all agreed, was to place [illegible] inefficiency, he would now state what steps he contemplated taking to remedy this evil.—Mr. Masterman (on behalf of Mr. Burns) replied: *My right honourable friend is not empowered to fix standards of disinfectants* and it does not appear to him that he could usefully take action in the matter. I may add that there is little public advantage in the domestic use of disinfectants as deodorants. Where they are employed to remove infection, they are commonly employed under the advice of a medical officer of health, or other medical man, who would be trusted to order disinfectants which are efficient.

Accidents in Mines.

Mr. Glover asked the Secretary of State for the Home Department whether he could state the number of serious accidents reported to the inspectors of mines during the years 1903, 1904, 1905, 1906, 1907, and 1908, and the number of non-serious accidents during 1908.—Mr. Gladstone furnished the following written reply: The figures of fatal and non-fatal accidents reported to the inspectors of mines during the years mentioned are as follows:—

Number of Fatal Accidents Reported.

Year.	Coal mines.	Metalliferous mines.	Quarries.	Total.
1903	1036	25	90	1151
1904	1017	31	110	1158
1905	963	43	97	1103
1906	1065	33	92	1190
1907	1162	33	88	1283
1908	1137	36	90	1263

Number of Non-fatal Accidents Reported.

Year.	Coal mines.	Metalliferous mines.	Quarries.	Total.
1903	3606	250	1373	5229
1904	3512	232	1278	5022
1905	3380	245	1193	4818
1906	3592	214	1337	5143
1907	5599	281	1459	7339
1908	5588	247	1515	7350

The figures for the year 1908 are preliminary and are subject to correction. The totals of fatal and non-fatal accidents reported were: 1903, 6380; 1904, 6180; 1905, 5921; 1906, 6333; 1907, 8622; and 1908, 8613. I have no information as to non-serious accidents in 1908. I should point out, as regards the figures of non-fatal accidents, that in the case of certain classes of accidents (e.g., accidents caused by explosion of gas or dust, or any explosive, &c.), all are required to be reported, whether causing serious injury or not, and also that the requirement as to reporting non-fatal accidents was extended by the Notice of Accidents Act, 1906, so that the figures for the last two years are not comparable with those for the preceding years.

Thursday, April 22nd.

Inquests in County Dublin.

Mr. Patrick O'Brien asked the Chief Secretary to the Lord Lieutenant for Ireland in what circumstances two inquests were recently held by the coroner for the southern division of the county of Dublin in licensed premises in Ranelagh, *having regard to the fact* that the Rathmines urban district council a few years ago erected a morgue on a site at the rear of the town hall, with the express view of putting a stop to the practice.—Mr. Birrell answered: I am informed by the coroner that in both cases the inquest was held in licensed premises because the circumstances were such as to render it advisable to have the body viewed in the place and position in which death occurred. Had the inquest been held in the Rathmines morgue, the jury would have had a considerable distance to walk to view the body which would have caused them great inconvenience and considerable delay. The coroner adds that the Rathmines morgue is a great advantage to the district and that he always avails himself of it when circumstances permit him to do so.

Unvaccinated Children in Schools.

Sir Maurice Levy asked the President of the Board of Education whether the managers of endowed schools, either of schools assisted out of the rates or [illegible] refuse admission to [illegible] nated condition [illegible] power to exclu[illegible] admission, solely on the ground of his [illegible] and, in the event of the managers having such power, whether he would add a clause to the next Bill dealing with educational matters which would remove such a disability from unvaccinated children.—Mr. Runciman (by written answer) replied: *I am advised that* governors of endowed schools regulated by schemes made under the Endowed Schools Acts and Charitable Trusts Acts are not as a rule prohibited by the scheme from excluding an unvaccinated child if they consider that so to do would promote the welfare of their trust But in the case of schools, whether endowed or not, which receive grants from the Board under their secondary school regulations, the Board would not regard the absence of vaccination as a reasonable ground for the exclusion of a day pupil, though they would be unwilling to interfere with the discretion of the governors in the case of boarders.

The Medical Inspection of School Children.

In the course of a debate on the Civil Service Estimates, Colonel Lockwood asked the President of the Board of Education whether there was any prospect of relief being granted in the counties in connexion with the medical inspection of school children.—Mr. Runciman replied: That is not a matter on which I am authorised to say anything at the present moment. A deputation waited on the Prime Minister recently, and his reply is the latest Government utterance upon the subject.

Friday, April 23rd.

Education (Administrative Provisions) Bill.

Mr. A. E. Dunn moved the second reading of the Education (Administrative Provisions) Bill. He said that by passing into law the Education (Provision of Meals) Act, 1906, the House had already approved in the most emphatic manner of the principle of feeding underfed school children, and therefore it was undesirable to go into the general question at the present time. However, in order properly to understand the matter with which this Bill dealt it was necessary to recall the fact that recently an Act of Parliament had provided for the medical inspection of school children. Now, the Bill which he submitted to the House provided, first of all, for the inspection of school children with a view to ascertain what children in the school, if any, attended in an underfed condition. It did not rest with the medical inspector to move in the first instance. The Bill dealt very gently with the local authorities in this respect. It empowered three classes of persons to set the inspector in motion. Clause 1 declared that the education committee or a majority of the managers of the school or the head teacher might request the inspector to make an inspection. Clause 2 provided that when that medical inspector had made his report, and if that report stated that there were children in the schools underfed, then it should be the duty of the local authority to feed the children. That was practically in substance the whole of the provisions of this particular Bill. There were one or two minor matters referred to in it. Under the existing law there was a limit to a halfpenny rate for the purpose of feeding school children, but under the Bill, if it was found that to feed the children a halfpenny rate was not sufficient, then that halfpenny must become more. Another useful and important provision was that the medical inspector should annually make a general report as to the condition of the scholars in a school. Surely that would be an exceedingly useful report, and he was quite sure that the education authorities would find it so. It was proposed that the report should be open to the inspection of the ratepayers generally. He contended that in making the proposals contained in the Bill he had in no ways forgotten the undoubted powers of the local education authorities. He admitted that if all local education authorities had acted as the majority of them had there would be no need for the Bill, but the House in this case had to legislate to bring the minority up to the mark. All that he now asked was that the House should confirm the principle of the Bill. That principle was that it was desirable that those children going to school in the large cities—and some of the large cities were the chief offenders—should receive proper nourishment to be in a condition to benefit from the teaching and consequently should have a chance of becoming good citizens.

Mr. Tyson Wilson, in supporting the second reading, said that during the past winter the London County Council had fed 54,000 underfed children, and the standard it adopted was exceedingly low. *If a fair standard* had been adopted the number of children fed would have been practically double what it was. Therefore there must be some other power than that of the education authority if the children were to be fed.

Sir Francis Powell, in moving the rejection of the Bill, said that he had served on the Select Committee dealing with the question of underfed children in 1906 There never was an investigation more complete. Now, the first consideration which occurred to him was the extreme haste with which honourable Members were now pressing this extending Bill on the consideration of the House. He found in the report of the Board of Education a remark that the legislation on this subject had been in force for so short a period that it had not had sufficient experience to make remarks upon it. The majority of local education authorities had been doing their best to carry out the medical inspection of children. In his opinion, it was premature to interfere with the Act. He argued that the tendency of the Bill would be to check voluntary effort and would diminish parental responsibility.

Viscount Morpeth seconded the motion for the rejection. He said that he opposed the Bill because he believed that discretion ought rightly to be placed on the local authority. If there was to be a discretion, surely it would be more properly vested in the hands of a local authority than in the hands of a single medical man. Although he had the highest respect for the medical profession, he thought it would be a dangerous step to give them full control and power in this matter without check by the common-sense of laymen, whose decision should always be final. Clause 2 provided that "the medical inspector must thereupon report his decision to the local education authority." That was to say that his decision was to be final and binding. Under those circumstances surely it was a misnomer to call the local authority an authority, because it had no authority at all in the matter.

Sir William Collins said that he was inclined to share the view that the Bill would *not add to the dignity of the medical profession* if the

[illegible]

ceived, and might require, not only administrative, but legislative changes The questions of the feeding of school children and medical inspection hung together, and the House of Commons ought not to be asked to amend legislation passed so recently as 1906 and 1907 without far larger inquiries than had hitherto taken place He asked honourable Members to remember that they ought to be guided,

[illegible]

voluntary work.

Mr. RUNCIMAN (the President of the Board of Education), replying to the debate at a subsequent stage, said the proposals in this Bill might well be discussed on their merits. It had been introduced with the

[illegible]

provision of food not only throughout the school days but throughout the holidays. That would not be educational advancement but Poor-law relief. Under Clause 2 the medical officer had to determine whether a child was insufficiently or improperly fed There was no provision as to who the medical officer was to be, but not only he, but also the head teacher, was to undertake this duty. The head teacher was apparently to have a sum of money in his hands to disburse for the provision of food in certain cases. That

[illegible]

lent being overridden well-devised piece of his assent. On the that during the last ad great difficulties no knew the fear of local authorities that medical inspection would become costly. Much of that fear was grossly exaggerated. He had sometimes had estimates sent to him—they were purely estimates and nothing else—which ran the cost up to 5s. per child He

[illegible]

House add more to the conflict and confusion which already embarrassed Poor-law reformers. He was afraid, therefore, that he could not support the Bill which he believed would do harm in present circumstances. Honourable Members should leave to local public opinion and to local authorities the reasonable liberty which they had under the Act of 1906 and under which on the whole they had acted well.

On a division the Bill was rejected by 206 votes to 82.

WEDNESDAY, APRIL 28TH.

The Sleeping Sickness in East Africa.

Mr. REES asked the Under Secretary of State for the Colonies what steps had been taken under the agreement and protocol between England and Germany with regard to sleeping sickness to preserve Nyassaland from this disease—Colonel SEELY replied: The agreement in question related only to Uganda and German East Africa. So far as Nyassaland is concerned, I am glad to say that the extensive investigations which are being made in the Protectorate have failed, up to the present time, to reveal the presence of the tsetse fly which transmits the disease These investigations will be continued, but there is good reason to hope that Nyassaland is not exposed to the risk of an epidemic similar to that which has wrought such havoc in Uganda.

tonic, but we trust that the West-end chemist who is the repository of this therapeutic treasure will second Mr. Bodkin's laudable reticence and not divulge the secret of a remedy which will add another terror to the perplexities of the medical referees of insurance companies, however great the temptation to launch a new patent medicine on the public. Yet it would be interesting to hear whether the latest elixir of health masked a murmur in Harcourt's aortic valves or merely abstracted some albumin from his urine.

A CURIOUS ACCIDENT.

A correspondent (a medical man) sends us an account of a curious accident which occurred recently on golf links in the south of England. A player whilst in the act of striking a ball managed to swallow "a quarter of a lighted cigarette" with no ill-effects. The eating of lighted candles, made, we believe, of apples with "wicks" cut out of almonds and soaked in oil, was a favourite performance of old-fashioned conjurers, and the consumption of chocolate cigarettes is doubtless still practised by the young. But the swallowing of lighted tobacco is not so safe a performance, and we congratulate the golfer on having taken no harm. Considering the concentration, both muscular and mental, with which some golfers make their drives, and the frequency with which they balance lighted cigarette ends between their lips while striking, we can conceive that this is not the first time that the accident has occurred.

AXILLARY AND RECTAL TEMPERATURES IN NEUROTIC SUBJECTS.

From a series of observations made by M. Erlandsen, a pupil of Professor Gram of Copenhagen, it would appear that there is no greater difference between the axillary and rectal temperatures in hysterical and other neurotic subjects than that which ordinarily obtains in healthy persons. This increase of difference was suggested by Dr. Hallager, a Danish physician, some years ago as an aid to diagnosis, and Professor Gram felt anxious that the value of the so-called Hallager's sign should be tested. M. Erlandsen therefore examined 89 patients suffering from hysteria, neurasthenia, traumatic neurosis, paralysis agitans, sciatica, chorea, and exophthalmic goitre, with great care and extremely sensitive thermometers. One of the first things that struck him was that a higher reading was obtained when the thermometer was inserted in the rectum to a depth of three centimetres, when the bulb was grasped by the external sphincter, than when it was inserted to a depth of seven or eight centimetres. The lowest difference between rectal and axillary temperatures was 0·12° F. and the highest 0·32° F., the mean being 0·14° F. There was only a small difference in persons having a rigid perineum—e.g., children, virgins, and adult men, the maximum occurring in multipara. In the 89 pathological cases M. Erlandsen found, when he took the observations himself, that there was a mean difference between the axillary and rectal temperatures of 0·68° F., which figure agrees fairly well with those given by different authorities, which vary from 0·77° to 0·93° F. Another rather important point is mentioned, and that is, that in fat subjects there is more difference than in thin persons between the axillary and rectal temperature, the reason being, according to M. Erlandsen, that the axillary space in fat persons is more isolated from the central parts of the body by the layer of adipose tissue being thicker. Be the explanation what it may, he found by dividing his subjects into three classes—fat, medium, and thin—that the mean differences between the axillary and rectal temperatures were 0·918°, 0·65°, and 0·59° in the three cases respectively. M. Erlandsen's original paper appeared in *Hospitalstidende* for Nov. 25th, 1908.

◆

R.A.M.C. points out that in the various advertisements of German "Cure Establishments" and Medical Institutes the tariff for baths and residence is never mentioned. He has found that in one well-known German spa at least the rates are very high, and inquires whether there are any such institutions offering a tariff comparable to the lower prices of English "hydros." It must be remembered that the treatment at such foreign institutions is of a special kind, and that the majority of people who proceed abroad for "cures" belong to the well-to-do classes. Both of these circumstances naturally tend to keep the level of continental "cure-house" charges at a high average, but we should be glad to hear of any properly vouched for establishments offering specially moderate terms which may be of interest to our correspondent and to other medical men.

Moribund has raised an interesting point with which we will deal in an early issue.

Communications not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Leeds Mercury, Jersey Evening Post, Liverpool Express, Weekly Despatch, Dundee Advertiser, Evening News, Newcastle Journal, Daily News, Northern Daily Mail, Birmingham Post, Edinburgh Evening Despatch, Glasgow Herald, Dublin Times, Midland Evening News, Walsall Advertiser, Yorkshire Observer, Birmingham Despatch, Aberdeen Evening Express, Morning Advertiser, Nottingham Guardian, &c.*

WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM, 73, Welbeck street, W.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY.—3 45 P.M., Lecture —Dr. A. Wylie · Larynx.
FRIDAY.—3.45 P.M., Lecture —Dr A Wylie: Larynx

OPERATIONS.

Ormond street (9 A.M. and 9 30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1 30 P.M.), and the Central London Ophthalmic Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

(Taken daily at 8 30 a m by Steward's Instruments.)

Lumleian Lectures

ON

RHEUMATIC FEVER AND VALVULAR DISEASE.

Delivered before the Royal College of Physicians of London on March 23rd, 25th, and 30th, 1909,

BY NORMAN MOORE, M.D. CANTAB., F.R.C.P. LOND.,

SENIOR CENSOR OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON; PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

LECTURE III.[1]

Delivered on March 30th.

PROGNOSIS AND TREATMENT.

MR. PRESIDENT, CENSORS, AND FELLOWS OF THE COLLEGE,—The book called Προγνωστικόν in the Hippocratic writings seems at its beginning to promise to treat its subject in the widest sense in which the word can be used. *τὸν ἰητρὸν δοκέει μοι ἄριστον εἶναι πρόνοιαν ἐπιτηδεύειν.* "He seems to me to be the best physician who knows how to know beforehand what will happen." "He will treat diseases best when he shall be able from knowledge of the patient's actual state to foresee the condition of the future." These are sentences of the preamble, but as the book goes on the subject is restricted to acute diseases and to a discussion of the interpretation of symptoms, not as bearing on particular maladies, but of the meaning of symptoms in relation to all forms of acute disease. The famous passage on the Facies Hippocratica occurs in this book, and, well known as it is, I will venture to quote it, since it is a perfect illustration of how the Prognosticon deals with its subject:—

> [illegible] yellow, or black, or livid, or leaden. If from the onset of the disease the countenance shows these [illegible] not furnish sufficient suggesti[illegible] hath long watched, if he has l[illegible] [illegible] f the patient remembers no such cause [illegible] to an end within that time it must be [illegible]

Gnashing of teeth, movement of the hands, rapid breathing, sweats, the state of the hypochondrium, pulsations in the [illegible] the hands and feet, sleep, [illegible], vomiting, expectoration, [illegible] in the head, sore throat, returns of fever—all these are discussed in their most general application to acute disease. The only special application to any single morbid condition is in the remarks on pneumonia and empyema. I may mention incidentally, because I do not remember to have noticed that it is pointed out in [illegible] as that [illegible] ttempt [illegible] good or evil of particular symptoms. At the present day the word *prognosis*, I observe, *generally suggests to the practiser or* student of medicine a single inquiry and no more. Will the patient live or die? A sounder use of the word is to include under it the whole probable future of the disease after the diagnosis has been made in each particular case. The constant practice of such a way of considering each case is certainly to the advantage of the patient, for it cannot but have an important effect upon his treatment. It is in this sense that I propose to apply myself to the consideration of the prognosis of rheumatic fever and of valvular disease.

The first question to be discussed is the duration of rheumatic fever. How long does the organism continue to live on in the endocardium? Does it after an attack die out of its condition of *multiplication, so that we can say the* disease is absolutely at an end, as does the pneumococcus of pneumonia? Or does it, like the tubercle bacillus, live on indefinitely in the body, maintaining its lodgment, for a time n[illegible] nd doing more injury, [illegible] first ten cases you m[illegible] they throw on this question?

A girl, aged six years, had rheumatic fever in September, 1905, and was in St. Bartholomew's Hospital for six weeks. She came in again in December, 1905, for six weeks. She was an out-patient for six months for her consequent valvular disease, mitral regurgitation, and [illegible] t pain. Then came [illegible] ust, 1907, onwards, [illegible] fever and was re-[illegible]

Is not the appearance of such a case as regards its lasting but intermitting effects very like one of tuberculosis? Would anyone doubt with such a history of manifestations in a case of tuberculosis that the whole was due to the effects of the original settlement of bacilli in the body? Would the intermission of raised temperature and of other symptoms from August to December in the second year give rise to any doubt *on the subject of the whole being one attack of tuberculosis?*

A woman, aged 24 years, had well-marked rheumatic fever in July, 1903; in March, 1908, she had had an attack and had had one in 1904.

Supposing this patient had had hæmoptysis in 1904 and well-marked pulmonary symptoms in March and July, 1908, should we not have expected to find tubercle bacilli in her sputa in July, 1908, and should we not be certain that her illness began in 1904?

A woman, aged 25 years, who came into St. Bartholomew's on account of palpitation and shortness of breath in January, 1908, had [illegible]

If this patient had had dysentery in India in 1899, had got over it and had returned to England, and had been admitted to the hospital in 1904 with a chronic diarrhœa, with blood and mucus discharged from the bowel, and after treatment had got well and left and had come back again in October, 1906, with a similar diarrhœa, and if after seeming to recover she had now and then passed a little blood and mucus, would not much the most probable explanation be that her Indian infection was the cause of all the prolonged symptoms and that if she died we should find imperfectly healed old ulceration with scar tissue near it in the large intestine? Should we not venture to state as we went round the ward that that anatomical change was then present in her intestine and that the whole dated from her attack of dysentery in India in 1899?

A woman, aged 24 years, was admitted to one of my wards on Oct 3rd, 1903, with rheumatic fever, of which the pains had begun on Sept. 21st. The pain and swelling of joints were well marked and she had mitral regurgitation. In 1900 she had chorea which lasted for seven months.

Might not this case be compared to that of a patient who had an attack of pleurisy on the left side, the nature of which was undetermined at the age of 16 years, and who had developed well-marked tuberculosis of the lung on the left side at the age of 24 years? Would it not be possible that the original infection had remained, that the pleurisy was due to a settlement of the tubercle bacillus which had since been so inactive as to produce no symptoms noticed by the patient, and which in 1908 under some favouring circumstances had been able to grow and produce the tuberculosis? If the original pleurisy had been shown to be tuberculous should we not at once admit that the tubercle of the lung eight years later was a probable development of the same infection? I have chosen this comparison because while we cannot be certain that an attack of chorea which we have not witnessed was of the variety which undoubtedly belongs to the series of phenomena of rheumatic fever, the presumption is strong that any chorea which occurred in the early life of a young patient with rheumatic fever was of that variety.

A woman, aged 24 years, was admitted to hospital on July 8th, 1903, [illegible]

---

[1] Lectures I. and II. were published in THE LANCET of April 24th (p. 1159) and May 1st (p. 1227), 1909, respectively.

No. 4471.

In the absence of an exact history of each attack and of the intervals we can only apply our knowledge of the frequency with which some pains appear between serious attacks, and the probability seems to be that this was one long period of rheumatic fever—that is, not of continuous fever, but of continuous disease due to the original infection, and to the constant presence of the organism to which rheumatic fever may be believed to be due.

A woman, aged 18 years, was admitted to hospital with rheumatic fever on August 24th, 1903. She had mitral obstruction and regurgitation. She had been admitted on three previous occasions with rheumatic fever and had thus had it under observation in 1893, 1900, 1902, and 1903.

Here again, if the analogy of tuberculosis has any force it may be applied to enable us to accept the probability that a particular organism was present in her system, probably in her endocardium, for ten years.

A boy, aged 16 years, was admitted to hospital on April 24th, 1907, with rheumatic fever. He had at the time mitral regurgitation and aortic obstruction and regurgitation. In 1896, when aged five years, he was in bed for six months with rheumatic fever; in 1897 he had chorea for seven weeks; in 1898 rheumatic fever; in 1899 rheumatic fever for eight weeks, and in 1904 another attack.

Supposing this boy had acquired the hæmatozoon of tertian ague in a malarious region in 1896 and had soon after moved to a healthy part of England we should have had no difficulty in believing that a recurring tertian fever was due to the parasite. I have myself observed a case in which a tertian ague continued at intervals for nine years, and have read of longer liability to the fever. The possibility of obtaining the hæmatozoon from the blood of course supplies a test of the continuity which must be absent while the micro-organism of rheumatic fever is unknown.

A boy, aged 12 years, was admitted to hospital with rheumatic fever in January, 1907. He had mitral regurgitation. In the summer of 1903 he had had an attack of rheumatic fever and since had had pains in his joints with fever at intervals.

A boy, aged 11 years, was admitted to hospital with rheumatic fever and had mitral regurgitation. His present attack seemed to have begun on Nov. 1st, 1906, and he had a similar attack three years before.

A boy, aged nine years, was admitted to hospital with rheumatic fever on Sept. 24th, 1904. He had disease of both mitral and aortic valves. In 1903 he was in the hospital with rheumatic fever for nine weeks and was readmitted in May, 1904, and was under observation till the beginning of August.

The history in this last case for more than a year was nearly continuous, and in this, as in the former two, the analogy of a development of the tubercle bacillus may be used to explain the course of a disease dependent on the organism of rheumatic fever.

It would, of course, be easy to mention many more such cases, but I have perhaps said enough to satisfy you that there is nothing unlikely in the view that the several attacks of rheumatic fever from which so many patients suffer are really successive developments of an organism which remains in the endocardium throughout the series of attacks. Thus, using the word rheumatic fever for the condition present when this organism is in the system, whether developed or in a potential state of development, I arrive at the conclusion that rheumatic fever has a variable duration. It sometimes, though rarely, lasts two months and no more. It frequently lasts from three to ten years and may last longer still. A short attack is more probable after 30 years of age than before. A long attack is most likely to occur when the disease begins in early childhood.

The answer to the question whether the patient will live or die in the first attack must, of course, be that he will not die in it. The cases of death said to be due to a first attack of rheumatic fever are generally diminished in number when minutely examined. Thus, a woman, aged 26 years, in St. Bartholomew's Hospital, under the care of the late Dr. Reginald Southey, had a loud systolic murmur, plainest at the apex, and some swelling of the right knee and fever. She had been ill for seven days, and she died three days later. It was supposed that she had rheumatic fever, but the post-mortem appearances seemed inconsistent with this view, though the endocardium was affected, and there were no signs of ulcerative endocarditis. The pericardium was adherent and in one part was calcified. The whole heart was dilated. The endocardium of the right auricle showed 18 small white specks, circular and encircled by an area of engorgement. These seemed on microscopic examination to be localised hæmorrhages of old standing, but what their nature was not discovered. There were 250 in the right ventricle, some in the left auricle, and many in the left ventricle. The valves had no such specks on them, nor had they any recent growths on them, though both the tricuspid and the mitral were incompetent. There was a small patch of recent lymph on the wall of the left auricle. The peritoneal surface of the intestines, the kidneys, and the liver contained similar specks, and it seemed possible that the disease was, in fact, a pyæmia, and that these were minute abscesses of various dates. As the post-mortem examination was made in 1879 the test of cultivation was not used.

That the illness beginning with a first attack of rheumatic fever will ultimately by the way of valvular disease be the cause of death is true of a large percentage of cases. In a smaller percentage the valvular disease, while not itself the immediate cause of death, is a chief contributing cause in some such acute disease as pneumonia. In another group of cases of valvular disease descended from an attack of rheumatic fever, a pericarditis perhaps of the same infection, perhaps of a pneumococcus or other organism, is the cause of death. In a small percentage again the rheumatic fever is a remote cause of death, since it has prepared the endocardium to receive the infection of ulcerative endocarditis or of influenza. In ten cases of ulcerative endocarditis an endocardium damaged in long past attacks of rheumatic fever was found in five. Thus rheumatic fever must be regarded as leading to a large sacrifice of life in at least four different ways of death. Will the endocarditis certainly leave permanent damage to some valve or valves? To this the answer is that a small percentage of patients receive no permanent damage, that a further small percentage receive damage, the signs of which after a lapse of time disappear, but that a large proportion of patients do acquire permanent valvular disease. It must be added that the proportion of cases which do not end in permanent valvular disease may certainly be increased by judicious treatment, just as judicious treatment diminishes the mortality in enteric fever, and that the commonest cause of a further continuance of the disease is letting the patient get up too soon.

The true result of an attack of rheumatic fever on the valves of the heart cannot be determined till after the patient has been up and about for some time and the tone of the myocardium has been completely restored. The injury to the valves may then prove to be much less than was before expected, and now and then it may prove to be unexpectedly greater. The valvular damage can as a rule be accurately determined three months after the patient's convalescence. The commonest valvular lesion after rheumatic fever is mitral regurgitation. The more often the febrile attacks are repeated the greater will be the degree of injury to the valves. In every case of rheumatic fever it is safe to predict that there will be no permanent damage to the joints. These are the chief points in the prognosis of rheumatic fever itself.

The prognosis of the several forms of valvular disease may properly begin with the general statement that death in mitral disease tends to occur gradually with long-preceding dropsy, and that in aortic disease, while the same method of termination may occur, there is also the permanent risk of a sudden termination of life.

The post-mortem appearances of the heart in cases of gradual death from valvular disease show that it is the enfeebled or degenerate condition of the myocardium which is the cause of the general dropsy and of the patient's death. The post-mortem appearances in cases of sudden death with disease of the aortic valves sometimes include a degenerate myocardium but in other cases show muscular tissue in which degeneration has not begun.

The temporary recovery which patients make from a condition of cardiac embarrassment, even if associated with extensive general dropsy, shows that an enfeebled myocardium may attain strength again and be able for some time longer to do its work. If at the supposed end of an attack of rheumatic fever a patient is left with distinct mitral regurgitation what will be the effect of that lesion upon his physical future and in what ways is that future affected? The first danger before him is that endocarditis is merely dormant, a danger to be met only by taking the fullest pains to ascertain that the attack is at an end. Further, rheumatic fever always means increased injury to the first affected valve with the possibility of injury to other valves. Let us suppose that no further endocarditis occurs. The imperfection in the circulation caused by the damaged valve is likely to be remedied by hypertrophy of the parts of the myocardium affected, of which the left ventricle is part. The apex beat, therefore, is found lower down and further to the left than in a normal heart. The degree of hypertrophy of course depends on the difficulties to be overcome. To what extent will it go?

The heaviest heart due to mitral regurgitation alone which I have myself met with post mortem weighed 22 ounces. It was that of a man, aged 20 years, who had no chronic interstitial nephritis and no adherent pericardium or other valvular lesion than mitral regurgitation. The degree of hypertrophy in a man does not often make the heart exceed 16 ounces in cases of mitral regurgitation. A patient, aged 12 years, with mitral regurgitation may in the course of from six to eight years attain such a good working heart that he only feels the presence of the valvular lesion after great exertion. Alcohol will sometimes relieve the cardiac uneasiness which he feels after fatigue, and I have seen a few cases of chronic alcoholism which seemed traceable to the endeavour thus to overcome the sensations produced by an overworked heart with mitral regurgitation. The heart that has accommodated itself in course of years to a considerable mitral regurgitation will go on working well for years, and even into old age if it be not affected by fresh endocarditis of any kind and is not exposed to unfavourable conditions, of which too great physical exertion and prolonged mental distress or anxiety are the most important, and the next in importance such diseases as pneumonia and influenza. These are particularly dangerous to such hearts in two ways—the pneumococcus or the bacillus of influenza may attack the old damaged endocardium or they may originate pericarditis; and in either condition, besides the embarrassment due to it, considerable enfeeblement or further change in the myocardium must be expected and generally occurs. In this way such an attack is often fatal. Over-physical exertion seems to strain the muscular tissue and thus leads to great irregularity in the action of the heart, but rest and treatment may restore the heart to its former condition. Prolonged mental distress seems to have even a more severe effect on the condition of such a heart than too great physical exertion, and the restoration in such cases is often a matter of extreme difficulty. The condition of the heart seems directly traceable to the disturbance of the mind or of the feelings, and as the illness goes on with these unrelieved the condition of the heart itself seems to react on the mental state and to aggravate it. Such patients sometimes recover very slowly; sometimes the natural ultimate failure of a damaged heart seems hastened and they die from dropsy, but I have seen several in whom an attack of pericarditis—not extensive or with great effusion—terminated life.

In mitral regurgitation aches are occasionally felt in the heart wall, not confined to one spot but extending from base to apex. Very severe spasmodic pain is also sometimes felt which might be mistaken for angina pectoris, but when watched is seen to be different, in that it lasts a much [illegible] rs, and does not give any sense [illegible] h. The occurrence of simple [illegible] gia due to such an embolus are [illegible] of mitral regurgitation as also of aortic valvular disease and add further to the long list of the consequences of rheumatic fever.

If instead of merely allowing regurgitation the mitral orifice is greatly narrowed by adhesion of the flaps of the valve to one another, so that there is well-marked mitral stenosis, the patient will have a still less easy life, more palpitations, a more frequent sense of cardiac irregularity, and less power of work, and will altogether be in a more distressing condition, and one in which there are fewer possibilities of improvement by way of hypertrophy or in any way. The patient with mitral regurgitation, as we all know, may often live to old age; the patient with mitral stenosis very rarely indeed. The narrower the orifice the fewer will be the patient's years. The heart may be capable of very nearly regular action in a few cases, but even in these very little extra exertion is sufficient to make it embarrassed and very irregular. The lungs are permanently engorged and attacks of bronchitis are frequent. A distress which recurs after relief, and with each recurrence grows worse, is pain in the liver. The tenderness to the touch may be extreme and often there is a sense of stretching there which amounts to acute pain as the patient lies still. Sometimes there is a similar pain in the spleen. The urine becomes diminished in quantity and albuminous. The general discomfort may be increased by piles; ascites and anasarca of the legs and arms appear, and a continued reduction in the quantity of the urine which diuretics affect but little points to the constant engorgement and gradual hardening of the kidneys. Treatment and rest give relief, but it is rarely long-continued, and the patient's life, even if carefully regulated, consists of little more than longer or shorter intervals between painful attacks. At last the cardiac irregularity and tumultuous action are incessant, the dropsy becomes inveterate, the engorgement of the liver cannot be diminished any more, constant œdema of the lower lobes of the lungs is present, the imperfect aeration of the blood affects the brain, and the patient has temporary delusions when awake and dreadful dreams during restless and often interrupted sleep. Mitral stenosis is the most distressing of all the common forms of valvular disease. It gives the patient least ease and soonest terminates his life. If it has begun in the girlhood of a woman she seldom lives beyond 40 years of age if she is married and has children, or much later than 50 years if she lives unmarried under the most comfortable circumstances. I have seen very few men with mitral stenosis who reached the age of 50 years. I think it is the cares of a household rather than childbearing which makes the lives of married women with mitral stenosis shorter than those of spinsters, for during pregnancy the patient is often much less distressed by her heart than at any time, though after childbirth she sometimes perishes owing to the onset of a fresh endocarditis. The addition of tricuspid stenosis increases the obvious irregularity of the heart and adds to the distress and diminishes very much the duration of life. From each side of the heart simple emboli may be shot into the circulation and may produce hæmoptysis or hæmaturia, while other hæmorrhages may occur as results of venous engorgement.

The hypertrophy produced by mitral disease seldom increases the heart to more than twice its natural weight. That produced by disease of the aortic valves often does so and may be t[illegible] or even 38 ounces. [illegible] in mind in cases in [illegible] difficult to determine. If there is very great hypertrophy (and no other present cause, such as adherent pericardium or chronic interstitial nephritis), if with a heaving impulse the apex beat is in the sixth space and beyond the nipple line, then that hypertrophy alone makes it probable that aortic disease is present. Such cases generally terminate in a sudden death, and of all causes of transition from what seems fair health to immediate death aortic valvular disease is the most frequent. This sudden death may be very long deferred. Thus a patient who probably acquired aortic valvular disease in 1837, after a well-regulated life in which it rarely troubled him, died suddenly from his aortic disease while dressing one morning in 1900.

Angina pectoris is to be regarded as a likely incident in this form of valvular disease. Its occurrence at once, and generally correctly, suggests a near termination, but sometimes the patient goes on living a very long time. A man whose aortic valves became diseased between 1877 and 1880 found that hard mental work affected his heart soon after 1890 when he was 43 years of age, and in 1898 he had definite angina pectoris which never left him but continued for ten years. I have met with several other instances where a man who seemed likely to die very soon yet lived ten years under similar circumstances.

Such are a few of the points of prognosis in rheumatic fever and in valvular disease. They all involve a repeated consideration of the patient's state and of his account of it. In receiving such accounts of past attacks and pains a literal interpretation of words must not be used nor too much information expected. Johnson in his noble poem on the death of Levett, as he repeated it to Boswell—

> "In misery's darkest caverns known
> His ready help was ever nigh,
> Where hopeless anguish pour'd his groan
> And labour steals an hour to die"

—has a last line afterwards altered by him, which expresses with the force of true poetry an observation on human life made among those who can but just earn their living, the justice of which we, who have all of us known and respected in the wards of our hospitals many such people, can confirm. How many a man and woman have we seen who seemed barely able to spare the time to die and who had amid laborious occupations neglected to record in the mind or to remember illnesses not great enough to prevent going to work.

There is another cause which obscures a man's life-history and which makes him subdue the sensation of cardiac irregularity and go on till the time for resting his heart is almost past and degeneration of the myocardium has begun. Alcohol at this serious and fatal cost obscures his condition from himself and keeps him going when he ought to be in bed. It does much to obscure the gradual, and often to be relieved, course of the valvular disease due to rheumatic fever and leads men to think symptoms sudden which are in reality but the last steps of a very gradual descent. Cases of this kind, of which there are very many, tend to spread the belief that death from valvular disease is a more rapid process than it really is.

Such are the points of prognosis which have struck me most.

The treatment of rheumatic fever proposed by Sydenham was based on the theory that it was an inflammation supported by the observation that the blood drawn from the rheumatic patient presented the same appearances as that drawn from one with pleurisy, a condition then universally described under the pathological heading inflammation. His first proceeding was to order ten ounces of blood to be taken from the arm on the side affected. The next day the bleeding was repeated; after one or two days there was a third bleeding, and after three or four days more a fourth bleeding, which was generally the last. A cooling julep, which was little more than a draught of sweetened water, was to be taken at the patient's pleasure. The painful joints were to be relieved by a poultice of white bread tinctured with saffron or by the repeated application of a cabbage-leaf. The diet was one of barley and oatmeal broth, all meat or meat broths being absolutely forbidden. The patient was allowed to drink small beer, everybody's daily drink at that time, or ptisans of barley, liquorice, or sorrel boiled in water. He was to keep some hours every day out of bed. On the alternate days to the bleedings enemata of milk with sugar were given and for eight days after the last bleeding. After that a purge was to be taken in the morning and the same evening a large dose of diacodium in cowslip water. Then the patient was allowed gradually to return to his wonted way of living with one caution—that he should drink no wine and no spirits and should avoid salted and spiced meats and anything difficult of digestion for a long time. "Pains," says Sydenham, "will thus be lessened, but will remain about for a long time."

Dr. Peter Mere Latham, who wrote in 1845 and whose knowledge of the practice of his day went back to a few years before the battle of Waterloo, had seen rheumatic fever treated by bleeding, by opium (2 to 5 grains every 24 hours), by calomel, by colchicum, and by drastic purgatives. When he was a student at St. Bartholomew's Hospital from about 1810 to 1814 the treatment of rheumatic fever usual there was to give a dose of liquor ammoniæ acetatis three times a day and an opiate at night—a humane method perhaps traceable to the practice of the enlightened David Pitcairn. He himself thought bleeding expedient in many cases. His view about it in the reign of Queen Victoria was much the same as that of Sydenham in Charles II.'s. He had used opium with success, though as, unlike Sir William Gull, he had never thought it right to leave cases quite untreated, he had, he admits, no sufficient standard of comparison to tell him whether he had done more than relieve pain. On the whole, he thought that the best plan of treatment was that by large (10 to 20 grains) and repeated doses of calomel followed by purgatives. I was a clinical clerk at St. Bartholomew's Hospital about a quarter of a century after the end of Dr. Peter Mere Latham's active life in his profession, beyond which his honoured age lasted for many years. His method was entirely obsolete and the general method of treatment of rheumatic fever was by alkaline salts. This method and several others have since become obsolete, and for the present, so far as the Pharmacopœia is concerned, it seems clear that the salicylates are much more efficient than any remedy of past times. They lead to a rapid cessation of the pain and swelling of the joints, and when continuously administered in the dose proper to each patient over several weeks they seem, so far as the temperature chart and the absence of further symptoms enable one to judge to prevent the further development of the organism in the endocardium or to destroy it altogether. The difficulties of administration which occur in particular individuals can generally be overcome by a little ingenuity in prescribing. A more rapid extermination of the organism is desirable, and for this we have yet to seek a drug. For the present that which we have does a good deal for the relief of the patient's pains while it is not inoperative in the process of terminating his malady.

We rightly regard the keeping the patient sufficiently long in a condition of absolute rest in bed as one of the greatest modern improvements—as compared with the practice of past times—in the treatment of enteric fever, and I think we may believe that there is no practiser of medicine in England who fails to carry it out thoroughly. I wish to urge the importance of a similar unanimity with regard to rheumatic fever. My experience leads me to the belief that there is always fear of re-development of the disease if the patient is allowed to leave his bed till his temperature has been absolutely normal, without any rise whatever above the normal line, for three weeks at least from the last rise. After this he ought long to be watched day by day with the aid of a temperature chart; and if in the week of his leaving bed or later any definite rise is observed, he ought to go back to bed for a further three weeks If no rise occur he ought still to continue under observation for three months, if possible, taking salicylates or similar drugs in adequate but diminishing quantities, and all this time his life should be so ordered that no strain is put upon his heart. If he is a boy at school he is not to take part in games all this time. If he is at home he is to take carefully regulated exercise and to have one rest or more in the day as well as a long night.

Perhaps in hospitals it may prove that three weeks of normal temperature is not enough before allowing the patient to get up. This may be discovered when three weeks have come to be generally adopted as a minimum period. I am certain that an earlier day of getting up only leads to prolongation of the disease.

One point which I wish to urge about the valvular disease due to rheumatic fever is the importance, when we see such cases, of taking the temperature or asking for a temperature chart. Thus only can we be certain that endocarditis is not present and that our treatment ought not to require that the patient stay in bed. Most physicians have seen children who walked to the hospital and who had the day before played about who, when examined, had raised temperature and such marked alteration of cardiac sounds that it was certain they had had endocarditis for several days. Arthritis was, of course, present, but of some small joint and causing only a little pain. Thus, when seeing a case of valvular disease in a young person, the first question to which the observer must ascertain the answer is not, when had he rheumatic fever, but has he got rheumatic fever at present. Thus the observer will come to know whether he has to treat a condition of acute endocarditis or one in which he is to try to relieve the heart in difficulties which it suffers from this or that simple or complex valvular defect.

As to this last part of the subject, it would be obviously impossible within the limits of these Lumleian lectures to deal with it. If, like the accomplished Sir Charles Scarburgh, versed alike in medicine, in anatomy, in Greek, and in mathematics, I were to hold the lectureship for 38 years I might perhaps, if I had his abilities as well as his time, exhaust all that there is to be said on valvular disease in all its forms. Or if like the learned and judicious Dr. Richard Powell, the first describer of facial palsy, I were to hold the lectureship for ten years, I might make considerable progress in the statement of sound principles of treatment and the refutation of much that is foolish which has been said about it; but my measure is smaller and my course of lectures is finished. Your time and mine will not have been wasted if I have persuaded you, and through you our profession at large, (I.) that rheumatic fever is a single definite disease; (II.) that endocarditis is always an essential part of it; (III.) that its duration may extend over many years, and that these circumstances, but half demonstrated as they necessarily are at present, are still the safest indications of method in the treatment of the disease.

Lord Lyndhurst, the Chancellor, once said in conversation, "I consider that the worst exaggerator is the person who understates." The remark was original and wise. It is illustrated in the books of many writers on rheumatic fever. They understate the conclusions which their own experience would allow. I have tried to avoid this fault and to state the conclusions to which my own experience has led me without abatement and without reservation. I have ventured to risk the censure which might attend such a course because I believe that the adoption of these opinions would not merely lead to a saving of lives but also to the prevention of many of the fatigues, disappointments in work, checks in usefulness, and other inconveniences which follow the valvular disease consequent on the endocarditis of rheumatic fever.

An Address

ON

GALL-STONES,

Delivered before the South-West London Medical Society on Jan. 13th, 1909,

BY HERBERT F. WATERHOUSE, M.D., C.M. EDIN., F.R.C.S. ENG.,

SURGEON TO, AND LECTURER ON SURGERY AT, CHARING CROSS HOSPITAL; SENIOR SURGEON TO THE VICTORIA HOSPITAL FOR SICK CHILDREN; EXAMINER IN SURGERY AT THE UNIVERSITY OF LONDON.

GENTLEMEN,—When your President and Council did me the honour to invite me to address you this evening I decided that I would choose as my subject "Gall-stones." Among the reasons for my choice were the facts that gall-stones constitute one of the most frequent of all the many morbid conditions to which the human body is liable, that their existence and their causal relationship to many grave forms of disease remain in many instances unrecognised, at least for a considerable time, and my conviction that the aid of the surgeon in cases of gall-stones, often sought too late, cannot be summoned too early. Time will only permit me to deal superficially with my subject, as it is too vast for adequate description in one address. I have no intention of describing the technique of the various operations that may be employed, as I have been informed that my audience is essentially composed of general practitioners, not of operating surgeons.

Let me remind you that though biliary calculi are far most frequently found in the gall-bladder, yet they may be found within the liver itself in one of the rootlets of the hepatic duct. Such hepatic stones, I believe, are rare, and are discovered on the post-mortem, rather than on the operating table. I have been struck by the fact that the size and number of biliary calculi bear no relation to the symptoms which they may produce. The largest gall-stone that I have removed is this which I show you (from a patient under the care of Dr. Arthur Farr). It measures two inches in length and three and a half inches in circumference measured at right angles to its long diameter. The smallest amount of concretion was represented by half a saltspoonful of fine sand, and yet in this case the symptoms were so urgent that immediate removal of the gall-stones was recommended by Dr. A. H. Vassie and myself. As to number, gall stones may be solitary or very numerous. Solitary gall-stones are by no means rare; the three that I now show you were removed by me during the past year. They are all, as you will observe, pear-shaped or oval, and lack the facets so characteristic of [illegible] Biliary calculi [illegible] forms about [illegible] insoluble lime salts, held together by an albuminoid scaffolding.

Little is known of the mode of formation of gall-stones. The cholesterin may be derived from the bile by precipitation, as the latter contains only about 2 per cent. of cholesterin, but it is now commonly believed that the cholesterin, the bilirubin, and calcium salts, and the albuminoid framework, all owe their origin to catarrh of the mucous membrane of the gall-bladder (lithogenous catarrh) commonly, if not invariably, of microbic origin. I believe that in all cases microbic infection of the mucosa of the gall-bladder is the chief causal agent in the production of gall-stones. It acts by giving rise to inflammation of the mucous lining of the gall-bladder and ducts, and thus forming mucoid masses around which are deposited cholesterin, bilirubin, and lime salts.

I am convinced that typhoid fever is a potent cause of gall-stone formation. A history of typhoid fever has been present in more than a quarter of the cases upon which I have operated. I have found typhoid bacilli in the gall-bladder three years after all symptoms of this disease had ceased, and have operated upon cases of typhoid cholecystitis. If this be true of the bacillus typhosus, surely it is only reasonable to suppose that other microbes which may gain access to the interior of the gall-bladder, either by way of the common bile-duct from the duodenum, or possibly by the blood stream, may have the same power. It is by no means uncommon to find gall-stones apparently dating from an attack of gastro-duodenal catarrh. In nine out of ten of my gall-stone cases in which a bacteriological examination was made, micro-organisms, chiefly bacillus coli, bacillus typhosus, and staphylococci, were found.

Gall-stones, as is well known, are more common in the female than in the male subject, and in those over 40 years of age, who are stout and indolent. The proportion of cases [illegible] hospital patients, [illegible] who indulge freely [illegible] frequently among [illegible] rink alcohol, the reason being, I believe, that teetotalers are in general large eaters. A statement which is undeniable is that biliary calculi are many times more frequent in women who have borne children than in those who are childless. Few medical men seem to recognise how common biliary calculi are. From various statistics it is certain that they are found at necropsies in 9 per cent. of all adults and in 27 per cent. of women over 50 years of age. Though I have for many years been surgeon to a large children's hospital, I have only once found gall-stones in a child under 12 years of age.

SYMPTOMS AND RESULTS OF GALL-STONES.

With these preliminary observations, allow me now to pass under review some of the symptoms and results of gall-stones. In the first place, let me say that though I am a surgeon I admit freely that in a considerable number of cases gall-stones give rise to no symptoms, or perhaps I should say to none recognised by the medical attendant, and this especially in cases in which bile can pass easily into the intestine. How often has it happened that a necropsy has revealed a gall bladder containing many calculi, the presence of which has never been suspected during life. Such instances have, in my experience, mostly occurred in old patients. In many cases, however, stones in the gall-bladder give rise to many and diverse symptoms, and not infrequently produce results of extreme gravity. Allow me to remark that there is no morbid condition of equal frequency that is more commonly overlooked than cholelithiasis. When t[illegible] the patient enjoys freed[illegible] tion of gall-stones is [illegible] me to point out that we see many times a year cases of gall-stones which cause symptoms and which ought to be diagnosed as such, but are not. The reason of this failure of diagnosis is that the patient refers all his, or her, pain and discomfort to the stomach and not to the gall-bladder or liver. The great majority of patients, possessors of gall-stones, have, I am convinced, been treated for months, and even years, for dyspepsia, chronic gastric catarrh, pain referred to the epigastrium, and flatulent distension of the stomach—i.e., for the conditions of which they themselves complained, whereas the real cause of their suffering and ill-health was the presence of calculi in the gall-bladder. How frequently has every surgeon known the old woman who has for years been treated for indigestion and wind on the stomach until some new symptom drew attention to her gall-bladder, when the stones were removed, and all stomach troubles completely disappeared. My firm belief is that the majority of flatulent dyspeptic women who attend the medical out-patient room with such wondrous regularity to receive their weekly bottle of medicine are really suffering from gall-stones. I do not ex[illegible] right and that I[illegible] y side. Many of [illegible]-stones, suffer fr[illegible] in the right shoulder, or some part of the scapula, especially its lower angle. Nearly all of them complain of a feeling of nausea and of a distaste for food, at least at times; many complain of a pain in the gall-bladder region, but tenderness—i.e., pain on pressure over the gall-bladder—is not always to be made out. Bear in mind that the contracted gall-bladder may be at a considerable distance from the surface. In many patients, however, who complain of no gall-bladder tenderness this symptom may be elicited by pressing the fingers deeply under the liver during full expiration, and then asking the patient to take a deep inspiration.

Jaundice is quite the exception in cases of gall-stones, save when impacted in the common bile-duct. It has been entirely absent in more than 85 per cent. of my cases. We must distinguish between (1) inflammatory—i.e., microbic—jaundice, such as may result apart from cholelithiasis, e.g., may be a sequel of cholecystitis; and (2) lithogenous jaundice, which is at first, at any rate, a mechanical process and due to the blockage of the common bile-duct by a firmly impacted calculus. Lithogenous jaundice from this cause is seldom so marked as jaundice due to the pressure of a tumour from outside on the common bile-duct—e.g., cancer of the head of the pancreas. Let me mention in this place the ball-valve calculus in the common duct. Take a case in which a calculus has passed half-way down the duct. That part already traversed by the calculus is dilated by the passage of the stone and by the *vis a tergo* of the accumulated bile; jaundice results. Then the calculus slips back into the dilated duct segment and bile flows into the intestine; again the calculus drops down and obstructs the non-dilated segment of the duct, and this process repeats itself indefinitely. This is the explanation of the fact that in chronic common duct calculous obstruction jaundice may be but slightly marked or be entirely absent. Many a patient has a stone or stones in the common duct without any suspicion of the fact on the part of his medical attendant. Jaundice is of course absent in purely mechanical calculous obstruction of the cystic duct. It makes its appearance, as a rule, in from 18 to 36 hours after an attack of biliary colic when a stone obstructs the common bile-duct, but, apart from the ball-valve calculus mentioned above, in a certain proportion of cases in which the calculus appears to be firmly impacted bile is enabled to trickle past it, so that jaundice may be but slight or even absent. In cases of jaundice which have lasted for many days and are the result of obstruction of the common duct a distended palpable bladder indicates that the duct obstruction is due to some other cause than calculus, usually to cancer of the head of the pancreas. When due to calculus impaction the gall-bladder is usually shrunken to the size of a walnut or a filbert and cannot be palpated.

Biliary colic is the most prominent trouble in cases of gall-stones, but most gall-stone subjects never complain of biliary colic, as usually the calculi do not enter the ducts but remain in the gall-bladder. The gall-bladder is a wonderfully distensible organ. It can be made to contain a pint of water, forcibly injected down the cystic duct, without rupture. The muscular tissue of the gall-bladder exhibits a marked tendency to hypertrophy in cases of biliary calculi. The cystic duct has a length of one and a half inches and a diameter of one-tenth of an inch, the corresponding measurements in the case of the common bile-duct being double the length and two and a half times the diameter of the cystic duct. Remember that the common bile-duct opens into the duodenum at the ampulla of Vater by an orifice common to it and the pancreatic duct, and that at this opening there exists a fairly definite sphincter and a marked contraction of the lumen of the duct. Both the cystic and the common bile-ducts resemble the gall-bladder in their capacity of allowing their lumen to be greatly dilated under pressure from within. In biliary colic the gall-bladder, hitherto wonderfully tolerant, for some reason suddenly resents the presence of stones in its interior and contracts upon them with the view to their expulsion, when, provided that the stone or stones be larger than the diameter of the cystic duct, a series of phenomena occur constituting gall-stone colic, the agony of which is in many cases a memory for the rest of the patient's life. As the calculus is forced into the cystic duct this canal resists the distending invader forced into it by the *vis a tergo* of the contracting gall-bladder, aided by contraction of the abdominal muscles. The passage through the cystic duct is rendered the more difficult owing to the presence of the pseudo-valves (folds of Heister) in its interior. As a rule these folds interfere with the passage of a probe down the duct. Once the cystic duct has been traversed the agony becomes less intense owing to the larger size of the common bile-duct, but at the end of this canal there is a still more narrow strait to pass—i.e., the markedly contracted orifice of the duct at the ampulla of Vater. Gall-stone colic frequently occurs in the early hours of the morning—about 2 A.M.—and often after a big dinner. There are few things worse for the possessor of gall-stones than a big city dinner, and I have known a respected citizen of portly dimensions express his bitter regret, during the agony of the gall-stone colic, that he had not been content with sponge cakes and milk and soda, instead of overloading his stomach at a city dinner. The explanation of the hour of onset of the attack is the attempt of the gall-bladder to expel the bile into the intestine at the suitable time—i.e., when the food enters the duodenum. The onset of the attack is so sudden that I have more than once known it to be mistaken for a perforative lesion of a hollow viscus. From the gall-bladder as a centre agonising pains shoot in various directions to the epigastric and the umbilical regions, the right shoulder, and the inferior angle of the scapula. The agony increases with exacerbations, and lasts, as a rule, from five to 18 hours, though I have known it to continue for six days with hardly an intermission. Commonly, the temperature is normal, or subnormal, but at times it is considerably elevated and such a febrile rise is apt to lead to mistakes in diagnosis.

Vomiting is a fairly frequent symptom in all cases of biliary calculi and a usual one in biliary colic in which the contents of the stomach are at first alone ejected. Later the vomit may become bilious. Provided that the cystic duct be alone blocked bile can readily find its way from the liver down the hepatic and common bile-ducts into the duodenum and thence into the stomach. Should, however, the stone block the common bile-duct bilious vomit cannot occur. For the same reason in the former case the fæces contain bile and no jaundice results; in the latter, after a certain period, the fæces are unstained by bile, and jaundice and bile pigment in the urine appear.

Gall-stone colic commonly ceases as rapidly as it commenced, and the patient then experiences the delights of freedom from intense pain. In many cases this cessation of colic means that the stone has reached the intestine, but in others that, finding its passage through the cystic duct impracticable, it has dropped back into the gall-bladder.

During an attack of biliary colic the liver may be noticed to be swollen and the gall-bladder exquisitely tender to the touch. These symptoms slowly subside and then frequently an enormous amount of clear watery urine is passed. It is needless to say that after every attack of biliary colic the fæces should be examined with scrupulous care for the detection of calculi for at least a week after the attack. In intense colic faintness not infrequently overcomes the suffering patient. Rigors with high fever may occur in cases of gall-stones with or without biliary colic and may disappear so soon as the infected bile gains entrance into the intestine. The fever in such cases resembles malaria; it is markedly intermittent, the temperature, which may rise to a great height—e.g., 106° F.—falling to normal, or just above normal, a few hours later. This condition is usually due to a calculus impacted in the common duct, and is of serious account, as it indicates infective inflammation of the biliary ducts. A terrible termination to biliary colic is rupture of the gall-bladder, the cystic, or the common bile-duct with outpouring into the peritoneal cavity of infected bile and resulting septic peritonitis.

Treatment of biliary colic.—Commonly a hypodermic injection of one-third of a grain of morphia is given as the patient demands relief from his agony. Antipyrin in doses of 10 grains every hour until 40 grains have been given is, I am convinced, a useful drug. Hot fomentations over the gall-bladder are soothing. When the pain has been very agonising I have had encouraging results from administering chloroform and massaging the gall-bladder and ducts through the relaxed abdominal walls. This method I commend to you with confidence, but it must only be employed in cases in which all signs of inflammation are absent.

Fatal obstruction of the small intestine by a large biliary calculus I have only once seen. I was called to a moribund old woman who for seven days had suffered from intestinal obstruction evidently low down in the ileum. As she was dying I left her alone and death took place within an hour of my first seeing her. At the necropsy I found a stone of the size of a florin tightly impacted in the lower end of the ileum six inches above its termination. The patient's daughter assured me that her mother had never suffered from biliary colic, and this was explained by the fact that this was a solitary stone which had ulcerated into the duodenum, leaving an opening between the gall-bladder and this segment of the intestine.

A more frequent result of gall-stones is the presence of dense fibroid adhesions around the pylorus and the commencement of the duodenum, which so narrow these parts as to give rise to gastric dilatation and call for the performance of gastro-enterostomy. I have several times found gall-bladder, liver, duodenum, and pylorus imbedded in adhesions (in one case so dense as to simulate a neoplasm when examined through the abdominal wall), and have been enabled to give relief to the gastric symptoms by the performance of gastro-enterostomy.

Permanent Obstruction of the Biliary Ducts.

We have hitherto considered cases in which the gall-stone obstruction in either duct was only temporary. We now turn to such in which the calculus remains permanently impacted. When this happens in the cystic duct the bile no longer enters the gall-bladder, which may undergo various changes. It may dwindle to a shrivelled sac with thickened walls which may, in part, calcify; it may become distended with clear, ropy fluid derived from the mucosa until it attains so vast dimensions that it may be mistaken for an ovarian cyst or a hydronephrosis, or the fluid in the gall-bladder may become pus, and lead to perforation of the viscus and peritonitis. Much more serious is the case when the common bile-duct is permanently and totally obstructed by a calculus, for in such the bile is prevented gaining access to the intestine and jaundice results. This, however, not invariably occurs, for I have operated upon several cases in which the common bile-duct was, to all appearance, blocked by calculi varying in number from one to nine, and yet bile was able to find its way adequately into the intestine. It is noteworthy that in some instances the common duct is obstructed by calculi so completely as to cause jaundice, and yet the closest examination of the patient reveals no history of gall-stone colic. Complete blockage of the common duct may cause no symptom beyond jaundice with clay stools and slight hepatic enlargement. In other cases sooner or later ensue the results of infection—viz., suppuration of the biliary passages and gall-bladder, cirrhosis (biliary) of the liver, suppuration of the intrahepatic ducts, or of the liver substance.

Allow me now to direct your attention to infection of the biliary ducts and its results. Normally the entire biliary apparatus is sterile. I have (in *Virchow's Archiv*, 119. Band, 1890) shown that in animals the introduction of bile into the peritoneal cavity does not cause a fatal peritonitis, and that the bile is really free from micro-organisms. The bile, however, though sterile, has no antiseptic qualities, but is a suitable medium in which microbes may grow and flourish. Hence it follows that the entrance of pathogenic bacteria into the biliary passages is fraught with utmost danger. The ampulla of [illegible] may be foun[illegible] health washed out by the flow of bile, but the arrest of this secretion enables them to ascend the duct and thus to produce their baleful action. I am convinced that in such *cases ascending infection* is the rule, though I *do not deny* the possibility of infection by the blood stream.

Experimental ligation of the common duct may produce ascending infection of the biliary passages, especially if it be performed in the last inch of the duct. Here injury to the duct wall acts as a *locus resistentiæ minoris*. Ascending infection of the biliary passages is usually ushered in by rise of temperature, 101° to 105° F., with rigors and profuse sweats. The fever is markedly intermittent and frequently simulates malaria. Between the exacerbations the temperature may fall to the normal or remain somewhat elevated. In other cases, which are of serious omen, the temperature remains the whole time at or near its maximum, this being an indication that the infection has reached and seriously attacked the liver in addition to the extrahepatic biliary passages.

Angiocholitis.—In this condition the intrahepatic biliary ducts are involved in the infective process. On post-mortem examination the liver is found to be swollen, pulpy, and infiltrated with pus. Some of the pus lies in the dilated intrahepatic biliary ducts, some in real abscesses which have their origin in the periductal connective tissues.

Gall-stone cholecystitis is the result of ascending biliary duct infection attacking a gall-bladder containing calculi. Should the infection occur in a gall-bladder only recently occupied by gall-stones, the gall-bladder will form a definite swelling. If, however, it occur in a gall-bladder long the container of gall-stones and the subject of previous inflammation, the sac, now contracted and shrunken, will not be able to assume tumour dimensions. The fluid in the gall-bladder may be sero-purulent, purulent, or hæmorrhagic, and in cases of some standing the viscus itself is adherent to neighbouring viscera (the duodenum, the transverse colon, the pylorus). These adhesions are not infrequently dense and fibroid in character.

Regarding the question of diagnosis, let me draw attention to the value of radiography. In many cases my colleague, Dr. W. Ironside Bruce, has given me assistance of very real value and has confidently and correctly diagnosed the gall-stones present. In other cases he has reported that the evidence was inconclusive. Such have commonly been in fat patients, in some of whom I have found, in others failed to find, gall-stones. I think it only due to my colleague to say that in no case in which he has stated that calculi were present have I failed to find them. I conclude, therefore, that in skilled hands such as his a positive diagnosis has a positive value. In some cases of calculous cholecystitis there will be found just outside the margin of the right rectus abdominalis, at its junction with the costal margin, a swelling and in all a point of tenderness on deep pressure.

The treatment of calculous cholecystitis is purely surgical, and it may be laid down that no delay, once the diagnosis has been established, is permissible. My preference in nearly all such cases is for cholecystotomy with drainage of the gall-bladder, an operation that, except in gangrene of the gall-bladder, has afforded me results that leave little to be desired. Cholecystectomy, or extirpation of the gall-bladder, has always appeared to me to be a more serious operation and to lack the virtue of drainage of the biliary passages which cholecystotomy affords. I reserve it solely for those cases in which I fear that the gall-bladder wall is seriously compromised in whole or part. Cholecyst-duodenostomy—i.e., making an opening between the gall-bladder and the intestine (duodenum) or transverse colon (cholecyst-colostomy)—should, I consider, be rarely performed and should be reserved for those rare cases in which the common bile-duct obstruction cannot be relieved. I have in two such cases performed [illegible] ve personal experience of [illegible] ive you no information of [illegible]

[illegible] ion which I have not infrequently met with. Many cases are fortunately localised by adhesions and thus form encysted abscesses. Frequently the origin [illegible] I have twice last year opene[illegible] obtaining any history of [illegible] gall-stones were immediately passed by the incision and rapid healing resulted. In the other a biliary fistula resulted which persisted for five months. A large gall-stone was then felt with a probe at the bottom of the sinus. The sinus having been dilated, a large single stone was extracted with forceps and six weeks later the sinus closed.

Far more serious are the cases of acute generalised peritonitis in which infected bile is poured out into the peritoneal cavity owing to sloughing of the wall of the gall-bladder or of one of the biliary ducts. In my experience this is a very fatal complication. Of the five cases that have come under my care, three occurred during an attack of biliary colic, and I confess that in two I did not immediately recognise, amid the agonising pain of biliary colic, that perforation had occurred. In the remaining cases perforation of the gall-bladder took place without any history of biliary colic, and the diagnosis of perforative peritonitis was easily made, though I attributed it to a duodenal or gastric ulcer in both. One recovery out of five cases is my melancholy experience of this grave condition. Of biliary fistulæ the result of gall-stones I have seen but few which discharged bile externally, and rarely has the discharge been at all copious. Internal fistulæ—i.e., of the gall-bladder with the duodenum the more common form, or with the transverse colon—are not uncommon. In no case did an internal fistula cause apparent damage to the patient and in the majority the diagnosis was only made at the necropsy, the patient having died from some other malady.

Let me now briefly refer to those far from infrequent cases of relapsing cholecystitis of microbic origin which so closely simulate gall-stone cholecystitis but in which no gall-stones are found on incising the gall-bladder. I do so for this reason, that their treatment by cholecystotomy and drainage is almost as satisfactory as is that of those cases in which gall-stones are found. I will content myself with the history of a single case. My old friend and fellow student Dr. G—— was obliged to relinquish practice owing to repeated attacks of abdominal pain and ill-health. I saw him in consultation with Dr. W. Aldren Turner. It was clear that he was suffering from chronic appendicitis. I removed the appendix vermiformis, which was obviously diseased, and thought that all would now be well with my friend. Some months later he consulted me again and told me that though he felt much better he was not yet well. He was now certain that his abdominal attacks were of two kinds: one the symptoms of which were due to appendicitis which had disappeared since the offending organ was removed; the other, of less severe nature, still persisted and frequently recurred. Dr. Turner and I diagnosed infective cholecystitis and I drained the gall-bladder, which contained no calculi, with the happiest results. My old friend, who for two or three years had been unfit for work, is now, I am glad to report, in excellent health, and doing useful service as medical officer of health to a large district. This combination of cholecystitis and appendicitis is by no means unusual. I have frequently met with it.

Time will not permit me to enter into the interesting question of the relation of gall-stones to pancreatic disease. I may, however, remark that a stone impacted at the ampulla of Vater is a serious menace to the pancreas. The pancreatic secretion may be dammed back into the gland, ascending inflammation of microbic origin of the pancreatic ducts may occur, or bile may find its way into the duct of the viscus with grave results. It is well known that the most efficient treatment for chronic pancreatitis consists in drainage of the biliary ducts by way of the gall-bladder.

PROGNOSIS.

I would insist that prognosis in cases of gall-stones is most uncertain. No one can foretell the outcome of the condition. I have learned never to prophesy. Some of the cases in which the symptoms have been trifling have terminated in death. Some of the most threatening and ominous have made apparent recoveries without operation. Two cases in which attacks of biliary colic and cholecystitis had recurred over and over again for several years with marked jaundice, rigors, and high fever, and in which I gave a grave prognosis, owing to operative treatment having been refused, made ultimate recoveries after the passage of gall-stones per anum, one when the patient appeared to be almost *in extremis*. In one, however, grave loss of vision occurred owing to retinal hæmorrhages.

The most frequent causes of death are: (1) microbic cholangitis; (2) perforation of the gall-bladder and ducts; and (3) carcinoma of the gall-bladder. I have met with carcinoma of the gall-bladder in a definite proportion of cases of cholelithiasis and have never seen it as a primary growth apart from gall-stones. I am convinced that their irritation is the usual cause of carcinoma of the gall-bladder. I think I may fairly claim that every death from gall-stones is a preventable one, that early operations are very safe, that they avoid many and grave complications, and that drainage of the gall-bladder is practically never followed by the re-formation of calculi. Were the question put to me, "In what cases would you advise operation for the removal of biliary calculi?" I confess I would wish to answer, "In all." This, which I am convinced will be the treatment of the future, would probably induce the majority of my hearers to label me an extremist. Let my reply be: Let me ask you to tell me something about your patient? If he will assist you in your endeavour to keep him out of the hands of the surgeon, will adhere to simple living, avoiding alcohol and rich foods, will drink a tumbler of hot water, with preferably a little alkali in it thrice daily, and take a daily dose of Carlsbad salts to insure free movement of the bowels and relieve any gastro-duodenal catarrh, then let him, if he wish, postpone the operation, for such treatment tends in many careful patients to induce a condition of absence of symptoms, commonly mistaken by the patient for a cure. But even such an ideal patient would be safer with operative treatment.

Should, on the other hand, your patient be one of those who live to eat, and is intolerant of restraint, who will not carry out instructions but persists in over-loading his stomach with rich food and alcohol, far exceeding what is required by a middle-aged man, then surely disaster awaits him if he insist on retaining his gall-stones; and if, in the absence of any contra-indication, his medical attendant aids and abets him in his refusal of surgical relief he cannot absolve himself from blame should some grave complication endanger his patient's life.

In conclusion, I would insist that as soon as the medical attendant makes up his mind that operative treatment is indicated the less the delay the better for the patient. The operative treatment of gall-stones in the early stages of the disease is one of the safest and most beneficent of all surgical procedures. I am convinced that an early cholecystotomy is far less dangerous to the patient than the passage of a single stone *per vias naturales*. I know no operation more easy or more entirely satisfactory than an early cholecystotomy. I know few more difficult than choledochotomy or extraction of a stone from the common bile-duct in a long-standing case. In the latter, even if the stone be removed the dangers are by no means overcome, as infection of the biliary passages may persist or adhesions may cause trouble in adjacent organs, especially the stomach. My advice to you, therefore, must be that as soon as you have, with some assurance, diagnosed the presence of biliary calculi, and especially if you can satisfy yourselves that they have produced definite symptoms and are threatening to give rise to some complication, the earlier they are extracted from the gall-bladder the better for your patient's safety and for your peace of mind.

URACHAL CYST SIMULATING *APPENDICULAR* ABSCESS; ARRESTED DEVELOPMENT OF GENITAL TRACT:

WITH NOTES ON RECENTLY REPORTED CASES OF URACHAL CYSTS.*

BY ALBAN H. G. DORAN, F.R.C.S. ENG.,
CONSULTING SURGEON TO THE SAMARITAN FREE HOSPITAL FOR WOMEN,
MARYLEBONE ROAD, N.W.

OVER ten years ago I read before a meeting of the Royal Medical and Chirurgical Society a communication entitled "A Case of Cyst of the Urachus, with Notes on Urachal and so-called 'Allantoic Cysts.'"[1] Several years passed by, but I came across no further examples of urachal cyst in my own practice until last summer, when I revealed by operation a remarkable and, I must add, undiagnosed example of this form of tumour. It simulated appendicular abscess and was associated with arrested development of the upper part of the genital tract. I will relate this case and then dwell upon others recently reported by Mériel, Weiser, Binnie, Delore and Cotte, E. D. Ferguson, &c., adding an unpublished report of a cystic sarcoma of the urachus in the practice of my friend Mr. F. S. Eve. I shall discuss almost exclusively pure urachal cysts as distinguished not only from tumours which are not urachal, but also from cystic urachal fistula, which, like other forms of urachal fistula, is clinically and surgically quite different from urachal cyst. The consideration of the pure cyst, in itself somewhat complicated, is quite sufficient for a single paper. I will endeavour to explain how much has been added to our knowledge of these cysts since I reported my first case in 1898.

---

* A paper read at a meeting of the Surgical Section of the Royal Society of Medicine on March 9th, 1909.

[1] Transactions of the Royal Medical and *Chirurgical Society*, vol. lxxxi., 1898, p. 301.

Urachal Cyst Simulating Appendicular Abscess; Arrested Development of the Upper Part of the Genital Tract.

The patient, aged 17½ years, unmarried, applied to Dr. R. Drummond Maxwell at the out-patient department of the Samaritan Free Hospital on July 16th, 1908. She complained of tenderness and swellin [illegible] ssociated with a history of a sudc [illegible] region a month previously, and she was admitted into my wards at once. After admission I found that the relations of the swelling to adjacent organs could not well be defined until I examined the patient with the aid of anæsthetics under circumstances presently to be explained. The patient's mother informed me that the catamenia were established at the age of 14 years without pain or constitutional disturbance. The periods were always scanty and attended with very little pain, and the interval was about five weeks. The patient had never suffered from any neurosis before, at, or after puberty. On June 16th, one calendar month before admission, the menstrual flow appeared as usual, but was accompanied by violent pain never experienced before. The pain continued for two days and then it abated. The patient at once resumed her work, but the pain returned two days later and obliged her to take to her bed again. During the whole of the week before admission she was quite incapable of attending to her duties. Roughly speaking, as regards what could be made out before anæsthesia was employed, there was a fairly well defined, almost spherical, swelling in the right iliac fossa, slightly moveable and tender to touch. There was resonance on percussion over its outer aspect. The lower part of the swelling could be defined on rectal examination. I refrained from making a vaginal exploration until a consultation was held. Then it was found that the vagina was barely two inches deep. A kind of dimple could be defined at the blind extremity towards the right. The tumour did not bulge into the vagina. At the lower limits of the swelling was a tuberosity which lay behind the vagina and in front of the rectum. The temperature and pulse were low. The patient had never been laid up with any severe illness. Before the arrested development of the vagina had been detected appendicular abscess was suspected, but after the examination hæmatometra or hæmatosalpinx seemed equally probable. On July 21st the period began, as usual, about five weeks after that which preceded it. I found that there was no palpable increase of pain or tenderness in the tumour nor any appreciable increase or decrease in size. The show was unusually free. I decided to examine the patient under anæsthesia during the period in order to discover the channel which transmitted the menstrual blood into the vagina, and for other manifest reasons.

Examination under anæsthesia.—The patient was a fairly healthy but slightly anæmic blonde. Her manner and appearance were perfectly feminine. Though hardly over 5 feet in height she was well proportioned, broader at the hips than at the shoulders, and free from hair on the face. The breasts were well-developed; there was no areola round the nipples. The axillary and pubic hair corresponded to the [illegible]

FIG. 1.

urinarius were normally developed. There appeared, on the other hand, to be no hymen nor was there the least trace of carunculæ. The vagina formed a blind pouch about two inches deep; the rugæ were prominent. The vaginal pouch was distinctly deeper on the right side, whence dark menstrual blood was seen to issue. On stretching the adjacent mucosa with the fingers a crescentic fold with the concavity towards the left was detected. It covered the aperture whence proceeded the blood. A uterine sound could be passed into this aperture and pushed onwards for three inches upwards, backwards, and a little to the right, closely following the outer limits of the lower pole of the swelling, as could easily be defined on digital exploration from the rectum. (Fig. 1.) On bimanual palpation the swelling was found to be a well-circumscribed tumour, firm, oval, and as tense as a recent hæmatocele. It could be pushed a little downwards, yet even then its lower pole did not bulge into the vagina, but passed behind it. The tuberosity in the recto-vaginal septum discovered at the previous examination lay to the left of the menstruating tract. It felt like a small cervix. The nature of the case remained obscure. I kept the patient at rest for a week. The period ceased and the tumour remained stationary. There was one sharp attack of local pain on July 28th without any rise of pulse or temperature.

Operation.—On July 29th I operated, with the assistance of Dr. R. V. G. Monckton, Dr. S. H. Belfrage administering ether and chloroform. I made an incision in the middle line. The parietes were unusually vascular. After separating the recti I came across a thick membrane of doubtful character and lower down I exposed the wall of the bladder which extended for quite two inches above the pubes. The membrane was cut through and about half a pint of a perfectly clear fluid was removed; unfortunately, none was preserved. The fluid lay in a cyst behind the recti and anterior to the parietal peritoneum; the membrane through which I had made the incision being the anterior portion of the cyst wall. The cyst was connected with the bladder by a thick cord half an inch in length. The upper limits of the cyst lay close below the umbilicus. In exploring the upper end of the tumour I laid open the peritoneal cavity. The omentum adhered to the peritoneum investing the back of the cyst in this region. The intestines seemed healthy; there was no evidence of tuberculous disease, no free fluid, and no intraperitoneal tumour. Lower down some coils of ileum adhered to the parietal peritoneum behind the tumour. I endeavoured to define the relations of the cyst to the genito-urinary tract. A catheter was passed into the bladder and a few ounces of urine were drawn off. There was no communication between the cavity of the bladder and the cavity of the cyst; the thick cord between the two was clearly a portion of the urachus and I observed that it ran into and not over the cyst wall.

As might have been suspected from what could be defined before the operation, the cyst lay to the right of the middle line. On pressing against its wall on the right inferiorly, from the inner side, I detected a fusiform body, like a uterine cornu or a small but entire virgin uterus, lying in the position of the menstruating tract along which a sound had been passed a week before. Above this body thickened tissue could be felt, apparently a small ovary. The tuberous cervix-like body already mentioned could be plainly defined through the walls of the lowest part of the cyst. When thus explored it was found to be a distinct, fairly moveable structure, the left ovary or uterine cornu. On further palpation through the cyst wall the pelvic cavity felt quite free from any tumour or deposit. There certainly was no such thing as a collection of retained menstrual blood.

At this stage of the operation it became evident that the swelling, which disappeared entirely when I opened the cavity full of fluid, was a urachal cyst. That swelling—in other words, the cyst—had been the cause of all the patient's recent trouble. As there was no trace of a hæmatometra or hæmatosalpinx I did not feel justified in dissecting in the dark behind the cyst, amidst deformed structures in very uncertain relations to ureters, blood-vessels, &c., merely to make out the extent of arrested development of the uterus and appendages. It was with the cyst, therefore, alone that I had to deal. I knew of several objections to the draining of a urachal cyst, nor could I dissect away its outer wall, since, as I have just observed, its positive relations to malformed structures were very uncertain. For these reasons I simply trimmed away as much of the lining membrane as could be safely removed. Then I cautiously passed several fine catgut sutures along the substance of the outer wall and tied them, so that the cyst cavity was closed in. This outer wall was the muscular sheath of the urachus abnormally thickened, so that the manœuvre just described was easy and nothing was caught up behind the cyst. I transfixed the segment of the urachus which ran between the lower limits of the cyst and the bladder with a fine linen suture and tied it on both sides. It was then divided between the cyst and the ligature. As will be explained presently, it is fortunate that I transfixed the urachus instead of tying a single ligature round it as though it were an artery. I kept the portion attached to the cyst for microscopic examination. Lastly, the sheaths of the recti were united with interrupted fine linen sutures and the integuments closed with interrupted silkworm gut.

After-history.—During convalescence there was no difficulty in micturition, which was voluntary from the first, and no urine leaked through the wound. By August 7th all the silkworm-gut sutures were removed; the wound was by then well healed. There was at that date no trace of any swelling in the right iliac region or pelvis. The firm moveable body which lay until the operation below the lowest part of the cyst was found, on bimanual palpation, to be connected with the fusiform body to the right of the middle line.

During the summer vacation Dr. Maxwell took charge of the patient in my absence. He reported that up to the day of her discharge at the end of August there was no sign of leakage of urine through the wound nor any show of blood.

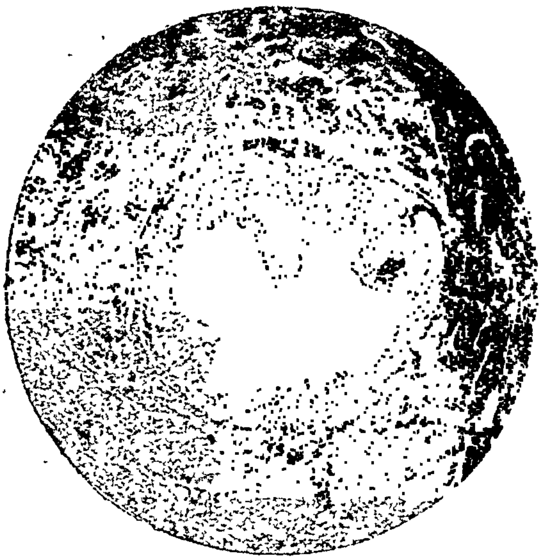
On Sept. 12th the patient came to see me at the hospital. Her general condition was good. A slight show of blood had been noted on the previous day, the first indication of a period since the operation. The abdomen was flat and free from tenderness. The cicatrix had completely healed. No trace of any abdominal tumour remained, the right iliac fossa was free; there was no resistant area or gurgling on pressure within its limits. No solid or cystic tumour nor any ill-circumscribed resistant body could be defined in the pelvic cavity. The fusiform body which transmitted menstrual blood and the firm moveable body on its left were now definable as one tough, smooth, irregular structure which could be pushed up to the level of the pelvic brim, slipping down immediately the examining finger was withdrawn. The mobility of this structure was very marked, the segment towards the left was not in the least tender, which would imply that it was the left cornu and not the corresponding ovary. Thus the urachal tumour had disappeared and no hæmatometra had formed, whilst the uterus was reduced to a right cornu which communicated with the vagina yet had no cervix, and most probably a left cornu connected with the right by a membranous band.

By the middle of October the patient was in very good health; she had been able to work for nearly four weeks, and a month later she reported herself as quite able to continue at her duties without feeling pain or fatigue.

I saw the patient once more on Dec. 15th. She was quite strong and able to work. The last period began on Nov. 26th and was moderate. The pelvic condition remained unchanged. Close above the fusiform body I could define the thickened tissue which I detected at the operation. It was slightly tender on firm bimanual pressure. There could be little doubt that it was the right ovary.

Microscopical appearances of the cord between the cyst and the bladder.—A section of the cord-like structure which ran on the surface of the parietal peritoneum between the fundus of the bladder and the cyst was made at the Royal College of Surgeons of England. There could be no doubt that it was a portion of the urachus. Mr. S. G. Shattock reported that the canal was quite patulous and lined with perfect transitional epithelium of the bladder type. The lumen was free from catarrhal or other morbid products. The muscular coat was abnormally thick but showed no evidence of inflammation or œdema. Its inner portion was mostly made up of circular and its outer portion of longitudinal fibres, but there was some irregularity in the direction of the fibres in both portions. Some subperitoneal fat was intimately connected with the periphery of the urachus. The appended reproduction of a photo-micrograph (Fig. 2) shows the above-described appearances of the urachus as seen under the microscope. The urachal canal, according to Wutz, is well developed in young subjects. In this instance it must have been closed at the bladder end, or if not there must have been an efficient Wutz's valve, as the contents of the cyst showed no evidence of being fouled by urine.

FIG. 2.



Section of the segment of urachus which passed between the bladder and the cyst wall as seen under a low power. The canal is quite unobstructed and lined with transitional epithelium. The muscular coat is very thick.

Having related this case, the second in my experience, I will now turn to the anatomy of the urachus, dwelling on certain peculiarities of importance in respect to the surgery of urachal cysts.

THE URACHUS.

The surgical anatomy of the urachus deserves more attention than it has hitherto received in this country. There is no necessity for us to slight the embryologists, indeed we can take on trust what A. Keith, Ballantyne, Bryce, Cunéo and Viau, and other authorities teach us, being fairly convinced that the urachus is developed from the allantois. There is likewise no need for us to disparage the labours of Bland-Sutton, Byron Robinson, Freer, and others who have demonstrated the pathology and surgery of urachal cysts and urachal fistulæ under their own observation. Let us rather turn our attention to a matter intermediate between embryology and pathology, in other words, let us study the anatomy of the urachus as revealed by special investigation of human subjects other than patients suffering from distinct disease of that interesting embryonic relic. Then, perhaps, we shall be better qualified to understand the pathology, diagnosis, and treatment of urachal cysts.

Wutz, so often quoted, stands first among writers whom we should follow as an example. In reporting my first case I noted his observations on the histology of the urachus based on 74 post-mortem subjects. He found that the epithelial tubular portion grows steadily up to the twenty-fifth year, the canal becoming wider, which is in accord with the appearances displayed by the microscope in the segment of urachus below the cyst in the present case. Passing over histological details, two important statements deserve to be noted. In 24 subjects in Wutz's series there were distinct cystic dilatations of the urachal canal, which contained pus in two instances where the patients had died from septic affections. Of equal importance is Wutz's statement that the vesical orifice of the urachus is guarded by a transverse valvular fold which under normal conditions prevents the passage of urine into the urachal canal. In 1898 I expressed my hopes that these researches would be followed up in this country, but up to the present Wutz has found but few imitators. We want to know more about the valve, for instance. Is it constant? The best recent work after the Wutzian method, as I may call it, has been undertaken by Binnie and Clendenning in America. I will quote in full their summary: "Mr. Clendenning recently examined for me 16 adult cadavers and 7 fœtuses, with the following results:—1. In 7 adults and 6 fœtuses the bladder showed a distinct diverticulum from 1 to 2 cm. deep at the fundus where the urachus is attached. 2. In 1 adult there was a *slight projection instead of a diverticulum.* 3. In 8 adults and 1 fœtus the dome of the bladder was smooth. 4. In none of the cases were there found lacunæ lined with epithelium in the urachus. 5. The average adult urachus was 12 cm. long by 1·5 cm. [*sic.* ? 0·15 cm.] wide. 6. The urachus was usually adherent to the belly-wall, but in one case (diabetic with frequent retention of urine) it was not close to the parietes but lay between loops of small intestine. 7. In all the cases the urachus was well supplied with vessels." Binnie adds: "Early in their development the urinary bladder and the urachus are completely surrounded by peritoneum except on their ventral surface where a meson (meso-cyst [2]) exists. This disposition usually disappears and the urachus becomes extra-peritoneal. That the meso-cyst sometimes persists was well exemplified in an adult cadaver examined for me in which the urachus did not lie close to the abdominal wall but lay between loops of small intestine. The persistence of the meson explains the occurrence of some otherwise puzzling intra-abdominal cysts." This case was the clinical evidence on which Clause 6 in the above summary was based.

The meso-urachus question is of high importance in respect to urachal cysts, especially those which have attained a large bulk. Delore and Cotte's researches were published almost simultaneously with the monograph prepared by the two American writers and, as will presently be related, they claim to have detected and removed a true urachal cyst that was intraperitoneal.

The French authorities quote Cunéo and Viau, who have found that in a section of an embryo 45 millimetres in length the intra-abdominal portion of the allantois and the *umbilical arteries are for the greater part completely invested* by peritoneum. This disposition persists when the allantois has begun to differentiate itself into urachus above and bladder below. It is, however, transitory, and the urachus becomes, as a rule, extraperitoneal in its entire length.

Professor A. Keith, conservator of the Museum of the Royal College of Surgeons of England, informs me that he has on several occasions detected a very considerable mesentery enfolding the urachus in adult subjects. He adds that under these circumstances the obliterated hypogastric arteries have even deeper and better marked mesenteries. Professor G. D. Thane has likewise observed this condition in several adult subjects. In these particular cases there was no evidence, I presume, that the mesentery was acquired, but Professor Keith tells me that he has never chanced to come across a meso-urachus in the new-born infant. Pathological evidence, as I will explain presently, does not lead us to believe that the urachus can acquire a mesentery after fœtal life. Mr. C. B. Lockwood reminds me that different observers are not agreed as to where a "fold" ends and a "mesentery" begins, but admits that the urachus may be invested in a fold of parietal peritoneum.

Thus, on the testimony and experience of independent embryologists, anatomists, and surgeons, we learn that the urachus may possess a mesentery or at least a fold of peritoneum, representing most probably the persistence of an embryonic condition. Still, we wish to know more about this matter and about Wutz's valve, so important in respect to the question of the precise relation of a urachal cyst to a cystic fistula connected with the bladder. Therefore, it were well if some British teacher of anatomy or pathology would follow the good example of Wutz and of Binnie and Clendenning. A series of several hundred subjects investigated after Wutz's method could hardly fail to furnish fresh evidence of high value.

The Urachus and Diverticula of the Fundus of the Bladder.

Although, for reasons given in the introductory remarks at the beginning of this communication, urachal fistula must be dismissed, I may be allowed to say a few words on abnormal prolongations of the urinary bladder upwards. Garrigues discovered, in a single woman, aged 45 years, who died after hysterectomy for fibroid, a bladder prolonged nearly to the umbilicus to which it was connected by a very short urachal tube. Balfour Marshall reports a case where a patent urachus over an inch in diameter formed a tubular prolongation of the bladder and was wounded when an abdominal incision was made for ventrofixation of the uterus, though without bad consequences. I turned attention to these *diverticula* in 1898,[3] and have noted *Binnie and Clen-*[illegible]. The surgeon will hardly trouble [illegible] of the bladder from a patent [illegible] y distinction. What concerns him is the fact that such a structure may be wounded during an abdominal section.

Tait's Pseudo-allantoic Cysts.

In 1898 I showed how the long series of cases reported by Lawson Tait had been misinterpreted by that great surgeon when he ranked them as urachal cysts, excepting one published by himself and Teichelmann in THE LANCET twenty years ago.[4] Several writers, who have apparently never read my criticisms, have recently expressed precisely the same views. Mériel, Binnie, and Delore and Cotte all maintain, as I did, that Tait's series were instances of encysted peritonitis, probably tuberculous, where, as I pointed out, communication between the bladder and peritoneal cavity is not infrequent. I may add that Mr. Tait himself, in a letter about [illegible] me that he had detected [illegible] the cyst wall in one case. [illegible] was a universally adherent ovarian dermoid, or a dermoid tumour derived from some other organ, but urachal it could hardly be. There were no after-histories to these cases and no verification of the relations of the cysts at necropsies. Hoffmann's case, where the cyst contained 50 litres of fluid when opened at the necropsy, was shown by Wutz to be an example of chronic hæmorrhagic peritonitis. The original report was so defective that an absurd error about the sex of the patient was included. Yet Delore and Cotte agree with Hoffmann, though rejecting Tait, and in articles on urachal cysts by living writers Tait's series and Hoffmann's equally spurious case are persistently included, as though they really represented urachal disease. The error seems, like King Charles the Second, a most unconscionable time dying. Let them be henceforth relegated to the archives of chronic peritonitis—in other words, to their proper place.

Cases of Cysts of the Urachus Recently Reported.

Two years ago W. R. Weiser published tables of nearly 90 reported cases of cysts of the urachus. These tables are indispensable for the study of their subject, but they show, as their author admits, that we cannot as yet draw from the literature of urachal cysts any sound conclusions such as may be inferred from published series of the ligature of big arteries for aneurysm, or Wertheim's operation, where at least there was always the aneurysm or the cancerous uterus to begin with. Weiser includes Tait's and Hoffmann's spurious cases and a considerable number of examples of cystic fistula, two being in his own practice.

Weiser's second case seems an authentic instance of a pure urachal cyst. It bore some relation to my own as it occurred in a young subject (a girl, aged 11 years). It gave rise to an acute attack of abdominal pain, headache, vomiting, and fever, and was markedly unsymmetrical. There was impaired resonance between the umbilicus and pubes from the left loin to about two inches to the right of the median line. When the abdominal incision was made the parietal peritoneum was found investing the posterior aspect of a large cyst which was connected inferiorly with a duct running into the bladder and patulous, let it be noted, to within three-eighths of an inch of the vesical cavity. The cyst almost filled the left side of the abdomen below the level of the umbilicus; it contained pus and had ruptured at one point into the peritoneal cavity. As much of the sac as could be dissected out without tearing through the parietal peritoneum was taken away, the cavity left behind was washed out and drained with iodoform gauze, and the patient recovered. Let it be noted that before the operation tuberculous peritonitis was suspected.

Whilst Weiser's own case is well reported, as I have [illegible] seen at a glance.[5] Let us trust that the next writer who takes the trouble to tabulate all recorded cases of urachal dilatation will carefully group under separate headings: (1) fistulæ; (2) primary cystic fistulæ communicating from the first with the bladder or opening at the umbilicus; (3) pure urachal cysts (the subject of this communication); and (4) secondary cystic fistulæ, developed from pure cysts which have acquired communications with the bladder or umbilicus. Surgicall [illegible] fourth as well as the second must be [illegible] from the third, hence I will pass over all statistics and will now proceed to the consideration of cases of pure urachal cyst published during the last ten years, but not included in Weiser's tables. That writer, I must add, omitted Bryant's two cases which were appended to my monograph in 1898. The first was a pure cyst in a woman, and simulated an ovarian tumour, the second was a cystic fistula, primary or secondary, in a male patient.

---

[2] This expression, meaning, of course, mesentery of the bladder, is best discarded, lest it should be taken to signify the mesentery of a urachal cyst.

[5] [illegible] se of cystic fistula reported by Unterberger. A woman had a bad fall during the first month of pregnancy. Acute backward displacement of the uterus occurred, the

The recent cases which I will now dwell on were under the observation of surgeons who, like myself, have enjoyed the advantage of studying the experience of others, and were thus the better able to avoid the fallacies which beset the original observer. It happens that these recent cases form a group fairly typical of every variety of pure urachal cyst, sessile on the bladder or separate, extraperitoneal or provided with a mesentery, incipient, moderately developed, or large—a most instructive series, in fact. We need not dwell on cystic dilatations detected in fœtal bodies, but as surgeons we must not disregard certain records of the accidental detection of small urachal cysts in the course of operations.

Small Cysts Detected at Operations.

Morestin, a few years ago, operated upon a woman, aged 24 years, removing a suppurating Fallopian tube. When making the abdominal incision he brought to light two cysts too small to be detected by palpation. One lay above the other in juxtaposition but independent, and they occupied the middle line behind the recti and in front of the peritoneum. The urachus could be seen running from the fundus of the bladder into the lower cyst and from the upper cyst to the umbilicus. The cysts did not adhere to the peritoneum behind them. They were tense, smooth, globular, and transparent. One was opened and found to contain a limpid, colourless fluid. The outer wall consisted of connective tissue, the inner was lined with pavement epithelium. Let it be noted that there was no trace of a meso-urachus, nor in either of the cysts which I have described, which were both of moderate size, was the tumour invested with peritoneum except posteriorly. This fact would lead us to believe, as was mentioned above, that a urachal cyst does not make for itself a mesentery as it develops. When a urachal cyst is intraperitoneal the urachus most probably had a mesentery before the cyst existed.

Again, we see that Morestin operated for pyosalpinx, a suppurative condition which was localised. When that condition is more diffused an incipient urachal cyst may be involved, as in two instances recorded by Wutz, to which I have already referred. Hence, it is always possible that an abscess in the middle line below the umbilicus may have developed in the urachus. Lastly, Morestin's cysts probably represented an incipient bilocular urachal cyst, like that which I described in 1898.

Mériel of Toulouse laid open a cyst of the urachus when performing a cystotomy for retention of urine. Its walls were thin, but distinctly thicker towards the bladder,[6] into the fundus of which it was inserted. The cyst had three walls, the outer of connective and fibrous tissue, the middle muscular, and the inner thin and smooth.

Lastly, the experience of Opitz is interesting to all who undertake abdominal sections. When performing what he calls a *relaparotomie*, in other words, when repairing an incisional hernia, he exposed a small cystic body which at first sight appeared to be a displaced and adherent vermiform appendix. On closer examination there could be little doubt that it was a urachal cyst. If so, it would seem that a segment of the urachus where the canal happened to be unobliterated was involved in cicatricial tissue at its upp and lower limits, the canal subsequently undergoing dilation owing to a collection of fluid and broken-down e thelium in its lumen. The main interest of this case however, as in Balfour Marshall's experience alrea mentioned, the manner in which the vagaries of t urachus and fundus of the bladder may puzzle the operat Whilst the little cyst in this instance simulated a vermifo appendix, the big cyst in my own case gave rise to sympto indicating appendicular abscess.

Cystic Tumours Removed by Operation.

In 1899 E. D. Ferguson operated on a man, 47 years age; his original report is very carefully written. T tumour rose to two inches above the umbilicus and extend laterally to the iliac spines. Its surface was flat, resista on pressure, and felt as though in the abdominal wall, y malignant disease of the omentum was suspected. T chief symptoms were hypogastric pain and frequent desi to pass urine. It proved to be a cystic tumour containi over two quarts of a watery fluid, which unfortunately w not examined; it was intimately connected with the wall the bladder and extended deeply into the pelvis, where t peritoneum lay behind it. Ferguson dissected away t whole lining membrane of the cyst, excepting at t umbilicus, where he found digital processes penetrating t tissues of the abdominal wall. "That portion of th posterior part of the cyst which could be placed in a fol and allow easy approximation of the peritoneum was stitch together and excised." The upper part of the abdominal i cision, close to the umbilicus, was drained with gauze and t remaining portion carefully sutured. Six months after t operation the abdominal cicatrix was found to be perfect sound.

Delore and Cotte's intraperitoneal urachal cyst, to which have already referred, is reported in their instructive mon graph on big cysts of the urachus. The patient was a gi aged 20 years, very sickly, and believed to be the subject tuberculous peritonitis of the ascitic type. There w uniform distension with distinct fluctuation. A large cy was exposed when the parietal peritoneum was incised; descended into the pelvic cavity. It contained blood-staine fluid and fibrinous masses, and when it was emptied an drawn through the abdominal incision Delore found that was connected below with the fundus of the bladder by short cord which formed an entirely extraperitoneal pedic and was clearly the lowest portion of the urachus. Whe the cord was divided the cyst was free of all connexions wit the patient's body. The broad ligaments and other peritoneal folds near the cyst were normal. The patient made speedy recovery. The outer wall of the cyst was the muscular coat of the urachus; the inner wall had been great altered and deprived of its epithelium by inflammator changes. The authors describe minutely how they found o careful dissection that the cyst was invested over the whol of its extent by the peritoneum, and that at the level of th attachment of the cord connecting it with the bladder thi fold of serous membrane ceased. A tough cord ran fro the pedicle over the anterior surface of the cyst and was los in the tissues of the tumour and abdominal wall at the leve of the umbilicus. In its middle portion this cord, like th cyst, was completely intraperitoneal. There can be littl doubt that Delore and Cotte's tumour was a cyst develope in a urachus which possessed a mesentery, an exception condition observed, however, as above mentioned, by mo than one writer in adult subjects where the urachus wa otherwise normal. The authors are probably correct in the theory that it represented the persistence of a fœtal co dition. That, on the other hand, a meso-urachus can b acquired is very doubtful, for reasons given above i reference to Morestin and Mériel's incipient urachal cys in adults.

The last in this series of recent cases has hitherto bee unpublished. Mr. F. S. Eve has presented to the Museum c the Royal College of Surgeons of England a unique specime of cystic sarcoma of the urachus and has kindly supplied m with the following notes:—

> A man, aged 38 years, was admitted into the London Hospital with [illegible] noticed for several weeks and associate [illegible] A cystic tumour filled the lower part c [illegible] he right, where it extended towards th [illegible] he pelvis. Mr Eve examined the specimen and found that it was a large allantoic cyst separated from the posterior superior surface of the bladder by nothing except a very much thinned mucous membrane Their cavities, however, did not communicate The inner wall of the cyst was lined at certain points with very vascular polypoid masses which proved on microscopical examination to be sarcomatous The most unusual feature of this cyst was its malignancy, but its peritoneal relations were of greater importance in respect to the subject of this communication

Aveling and Bland Sutton have already reported a case of multilocular myosarcoma of the sheath of the urachus, but it did not involve the urachal canal and was quite unconnected with the bladder. The specimen No 417B in the pathological series of the Museum of the Royal College of Surgeons of England was supposed, when first examined, to have developed in the urachus, but Mr J H. Targett considered that it was a myxo sarcoma which originated in the connective tissue surrounding the bladder

Mr Eve's cystic sarcoma seemed to possess a partial peritoneal investment, as in Delore and Cotte's case, but it was sessile on the bladder, whilst in the latter case the cyst was separated from the bladder by a segment of urachus In the instances of extraperitoneal urachal cyst above noted the tumour was sessile on the bladder in E D Ferguson's case, and so also was the bilocular cyst which I reported in 1898 On the other hand, in the case which is the subject of this communication the cyst and the bladder were separated by a segment of urachus These opposite relations of cyst to bladder were demonstrated respectively in the incipient tumours discovered by Morestin and Mériel

The malformation of the genitals, a unique feature in my case, deserves a little consideration After discussing it I will dwell once more on the extreme asymmetry of the cyst which together with the inflammatory complications in its neighbourhood simulated appendicular abscess In conclusion I will comment on the surgery of pure urachal cysts

Relation of the Urachal Cyst to the Arrested Development of the Genital Tract

In my case it was clear that there was not a cystic urachal fistula but a pure urachal cyst which was separated by a short cord, the lowest part of the urachus, from the bladder There was no evidence of malformation of the bladder itself, its fundus and anterior portion as well as the urethra were normal, nor was there any sign of abnormality in the ureters sufficient to interfere with their functions The structures making up the vulva were also well developed and the lower part of the vagina was present, nor had either genital gland strayed into the inguinal canal On the other hand, the upper part of the genital tract showed marked arrest of development The short canal, which transmitted menstrual blood into the right side of the blind end of the vagina, represented the upper part of the vagina, the cervix, and more or less of a right uterine cornu with its endometrium The firm, moveable body above and behind the blind end of the vagina was most probably the left cornu connected with the right by a thin band, as is not rarely seen in cases of uterus unicornis in parous women These relations were not difficult to define after the patient had recovered from the operation, and no cyst remained to interfere with bimanual palpation I admit that the body which felt like the left cornu might have been the left ovary, in which case the cornu would more probably be suppressed altogether I made out during the operation an ovary like structure close to the right cornu The presence or absence of the Fallopian tubes and the disposition of the pelvic peritoneum remain mysterious, though there was no trace of a hæmatosalpinx or a hæmatometra Although there were no external signs of hermaphroditism, I cannot say positively that both genital glands must have been ovaries Dr A. Broca recently operated for double inguinal hernia on a subject who was a female according to all external appearances [7] The vagina, clitoris, and hymen appeared normal, yet both genital glands were true testicles Each occupied a hernial sac

Some pathological change early in fœtal life must have caused the two abnormal conditions Professor Keith in his recent museum demonstrations at the Royal College of Surgeons of England explained how there was every reason to believe that disease of adjacent maternal structures, such as endometritis, prejudicially affects the normal evolution of fœtal elements derived from the allantois, and the same may be said of the gradual conversion of Muller's duct into Fallopian tubes, uterus, and vagina For the cystic condition of the urachus and the arrested development of the uterus in my case there must have been a common cause The urachal cyst presumably represented in a very mitigated form the arrest of development known when extreme as ectopia vesicæ [8] In this distressing variety of malformation and also in complete ectopia of the abdominal viscera non union of Muller's ducts has repeatedly been observed (E Chill, Author) According to A Keith the uterus is double in one out of six specimens of ectopia vesicæ in London museums, whilst in seven specimens of ectopia in females combined with an open yolk sac Muller's ducts are unfused in all

The faulty condition of the genital tract in my case was of little surgical interest, as it was not of a kind such as could be remedied by the knife or by some plastic procedure It was the condition of the urachus which demanded operative interference

Asymmetry of Urachal Cysts

In the present case the cyst lay in the right iliac fossa, the middle line forming its limits to the left Some intestine was adherent to the cyst on the right, so that there was resonance on percussion, and there was likewise local pain and tenderness Thus an asymmetrical urachal cyst may simulate appendicular abscess

Arguing without clinical evidence we might conclude that a urachal cyst would develop symmetrically This conclusion, however, is belied by experience In the remarks on recent reports given above it was noted that in Weiser's case the cyst filled the left side of the abdomen, whilst Eve's cystic sarcoma lay mainly to the left The cyst removed by Douglas of Nashville in 1897 was also asymmetrical, distending the abdomen chiefly to the right

This asymmetry becomes less surprising when we remember that it often exists from the beginning Delore and Cotte, speaking of minute urachal cysts as described by pathologists, observe that these dilatations sometimes involve the entire lumen and circumference at the point of the urachus where they develop, but that as a rule they affect only a portion and form true diverticula, which may become completely isolated from the canal of the urachus Thus the pathology of this asymmetry is very clear and its clinical importance quite evident.

Association of Urachal Cysts with Peritonitis

The symptoms of peritonitis in this case, where there was a conspicuous swelling in the right iliac region, indicated appendicular abscess Peritonitis had developed around an asymmetrical cyst of the urachus The first attack of pain occurred at a menstrual period, so that when the atresia was detected I naturally suspected retained menses But the

---

is condition In Bryant's

fistula (*vide s pra*) there

swelling did not increase during the next monthly period when the patient was under my care, and I found at the operation that it was not a hæmatometra or a hæmatosalpinx. We must therefore turn back to the local peritonitis. The patient in this case was evidently exposed to some unfavourable influence which caused peritonitis around the cyst.

In my first case, reported in 1898, the patient, aged 59 years, had been subject for nine months to pain in the lower part of the abdomen; the cyst was then detected, and symptoms of peritonitis came on periodically until two months later, when I operated. I find on referring to my original case-book that the menopause had become complete over nine years before—that is, when the patient was about 50. In fact, there is no reason to believe that the catamenia had anything to do with either case. In both I found omental and intestinal adhesions to the parietal peritoneum lining the back of the cyst. Other writers, Delore and Cotte, Weiser, &c., have reported similar complications. Indeed, peritonitis seems to be the rule when a urachal cyst has reached proportions sufficient to give rise to symptoms leading to its detection.

These symptoms appear very irregularly, which is one reason why *encysted dropsies* and *tuberculous peritonitis* are so apt to be confounded with urachal cysts. The error of mistaking the former for the latter, into which Hoffmann and Tait fell, has, as I have been at some pains to explain, greatly impaired the value of statistical records of urachal tumours.

Age.—In the present case the patient was 17 years of age, in Weiser's she was only 11 years, and in Delore and Cotte's 20 years. Urachal cysts are relatively frequent in young girls, and as they are likewise subject to tuberculous peritonitis and to inflammation of the vermiform appendix we can see how easily errors of diagnosis may occur.

Surgical Treatment of Pure Urachal Cyst.

Any communication between the interior of a urachal cyst and the cavity of the bladder, or the surface of the body at the umbilicus, greatly increases the difficulties and dangers of operative measures. It is partly on that account that I have confined my observations almost entirely to pure urachal cysts. Whenever it seems fairly clear that a cyst of this kind can be extirpated without the dangers of dissecting in the dark amidst uncertain relations posteriorly the radical operation should be undertaken. This, however, itself not free from risk even under the most favourable circumstances, is not always possible, as shown by the reports of many surgeons, whilst in the present case the posterior wall, for special reasons already given, could not have been safely separated from the abnormal structures in close relation to it. We must remember that in urachal fistula the insertion of the ureters into the bladder may be abnormally high (Mikulicz), and we are dealing with a malformation closely related to fistula. The surgeon must in many cases be content with partial measures which, as I have explained, were successful in Weiser's, E. D. Ferguson's, and my own two operations. As much as possible of the inner lining membrane must be dissected away; in the present case this was readily effected, but in my 1898 case it was impracticable, the membrane having been destroyed by degenerative changes. Partly on that account and partly because the tumour was bilocular I found drainage necessary. A sinus developed but closed within six months, nor did it ever open again. The patient died from cancer of the pylorus and pancreas six years later. In the present case there was no indication for drainage. The firm and fairly thick main wall of the cyst, fibromuscular or purely fibrous, is very favourable for treatment by whip-stitching or any similar plastic procedure suitable according to circumstances.

During the operation, complete or partial, the surgeon must always carefully ascertain the relations of the cyst to the bladder. If the cyst be sessile it may be impossible to remove it without damage to the walls of the bladder, which will therefore require repair by suture. When, on the other hand, the cyst is separated from the bladder by a segment of urachus, it must be remembered that the segment may have an open canal communicating with the bladder. The microscope showed that in the present case (Fig. 2) it was open, although there was no proof that it actually ended unobstructed in the bladder. Lest a urinary fistula should develop, as appears to have happened in a case described by Ill many years ago, that writer treats the divided segment as though it were a vermiform appendix, turning in its cut edges and applying a Lembert suture. In the present case I transfixed the segment and tied it as though it were a pedicle of an ovarian cyst. In any case, it should not be tied without transfixion as though it were an artery. The loop might easily loosen or come away, and the canal would then be patulous. We know that this may happen when the stumps of both Fallopian tubes have been ligatured in a double ovariotomy, as pregnancy has followed, which means that the canal of one tubal stump must have transmitted an ovum from the relics of one ovary. Should the ligature come away from the urachal stump a urinary fistula of a very bad type would develop if Wutz's valve were forced open by over-distension of the bladder. The risk of such a complication under these circumstances, and the fact that a pure urachal cyst in males is occasionally converted into a secondary cystic fistula full of urine, reminds the surgeon that, as I have already remarked, we ought to be more sure about Wutz's vesico-urachal valve, or whatever it may be, that really protects the vesical orifice of the urachus.

Granville-place, W.

THE ALCOHOL INJECTION TREATMENT FOR NEURALGIA AND SPASM.

By WILFRED HARRIS, M.D. CANTAB., F.R.C.P. LOND.,
PHYSICIAN TO OUT-PATIENTS AND TO THE DEPARTMENT FOR NERVOUS DISEASES, ST. MARY'S HOSPITAL; PHYSICIAN TO OUT-PATIENTS, HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE.

THE treatment of trigeminal neuralgia, or "tic douloureux," by means of drugs, electricity, vibration, percussion of the nerves at their points of exit from the foramina upon the face, and other devices of various kinds has always proved a failure in genuine severe cases of this extremely painful disease, ever since Trousseau 50 years ago drew attention to it under the title of "epileptiform neuralgia." Peripheral injection of the painful spots by means of osmic acid, chloroform, cocaine, &c., has given relief for short periods, varying from hours to a few weeks, but hitherto real relief has only been obtainable by means of surgical aid. Resection of the various branches of the fifth nerve, either peripherally at their points of exit from the foramina upon the face, or more centrally in the zygomatic fossa, or intracranially, has brought relief from the pain for several months or even years, the results being generally better the nearer the resection is done to the Gasserian ganglion. Permanent cure does not result from resection, as with the regeneration of the nerve fibres and consequent disappearance of the anæsthesia on the face which was produced by the division of the nerve the pain returns eventually with equal or greater severity, probably being hastened in some cases through the irritation of the nerve by the cicatricial contraction of the scar tissue resulting from the cutting operation. This scar tissue produced by resection operations makes a second operation at the same spot practically impossible, and consequently, when the spasms of pain return owing to the regeneration of the nerve it will be necessary to resect the nerve at a point nearer to the skull, or even intracranially Owing to the unsatisfactory results on the whole of resection the operation of extirpation of the Gasserian ganglion was devised and in the hands of skilful surgeons permanent relief from the pain has been obtained in a considerable number of cases It is, however, a very difficult operation to remove the ganglion completely, and, if only partially removed, the pain may continue unabated, or may return later The severity of the operation is, moreover, indicated by the percentage of deaths resulting from it, even in the most experienced hands, and the scarring and deformity produced by the operation are also disadvantages

It is owing to the introduction by Schlosser in 1903 of his method of deep injection with 80 per cent alcohol of the main trunks of the fifth nerve at their points of emergence from the skull that the principle of resection is again justified Injection of a nerve with alcohol of over 70 per cent strength causes immediate paralysis of the functions of the nerve, with the setting up of a degenerative neuritis extending from the point of injection to the periphery With a purely sensory nerve, such as the superior maxillary, the second division of the fifth nerve, anæsthesia will be produced over the area of the skin of the face and mucous membrane of cheek and gum supplied by the nerve, with at the same time more or less œdema of the skin If a mixed motor and sensory nerve is injected with the alcohol, such as the median or the sciatic, motor paralysis as well as anæsthesia will result—a fact to be clearly borne in mind when applying this treatment to such mixed nerves

This method of local destruction of the nerve fibres by deep injection of the nerve trunk with strong alcohol is in reality an extremely elegant method of resection of the nerve, and the after history of the cases is somewhat similar, inasmuch as regeneration of the nerve fibres takes place after several months, the anæsthesia gradually disappears, and in cases of severe trigeminal neuralgia the attacks of pain are likely to gradually reappear, the interval of freedom from the pain varying from four or five months to as long as 18 months or more The great advantage of the deep injection method over resection of the nerves lies in the absence of scarring and the consequent fact that injection of the nerve may be repeated at the same point an indefinite number of times Moreover, it is probable that after resection of a nerve the formation of scar tissue in the wound irritates the central end of the nerve after division and surrounds the new nerve fibres after regeneration, thereby tending to shorten the period of relief after division of the nerve, and also ultimately to increase the pain from irritation This factor is absent with the injection method as the track of the needle leaves practically no scar, and the point of entry of the needle on the cheek is in most cases impossible to identify a week after the injection Schlosser has also found, after an experience of 123 cases of trigeminal neuralgia treated by this method, many of them repeatedly injected at intervals for recurrence of the pain, that practically every case can be relieved by this procedure, that the average period of relief from pain obtained is over ten months, and that the interval of relief from pain obtained lengthens after each successive injection These facts alone are sufficient to warrant an extended trial of the method, and it has been a matter of surprise to me that no literature on the subject has appeared in this country, and that when I first began to use this treatment last August I could hear of no one else who had tried it, and indeed very few who had as much as heard of it On the Continent and in America many are using the mode of procedure, with apparently the same success as did Schlosser, and good descriptions of their modifications of the method of deep injection have been published in Paris by Ostwalt, and by Brissaud and Sicard

In the October (1908) number of the *Practitioner* in my review of neurological literature I gave a description of the treatment, and on Feb 25th, 1909 I read a paper on my experiences of the method on 13 cases before the Neurological Section of the Royal Society of Medicine, demonstrating the method on the skull, and I also showed two patients, both subjects of trigeminal neuralgia affecting the left second division of the fifth nerve, whom I had injected with alcohol four and a half months and three weeks previously respectively, with complete disappearance of the pain in each case Up to the present time I have used the alcohol injection treatment in 17 cases, six of which are cases of paroxysmal trigeminal neuralgia

Trigeminal neuralgia —In one case only, one of my earliest cases, did I fail to relieve the pain, due to my failing to reach the foramen ovale through faulty technique In this case the pain was mostly in the third division, affecting the lingual nerve, in a woman, aged 55 years, who had been subject to the attacks of pain for the past 17 years, for part of the time the pain being bilateral, a very rare condition in trigeminal neuralgia In each of my other five cases the pain has been immediately relieved, though the last case was done so recently as a week ago that it is premature to speak yet of a cure Of the remaining four cases, one patient—a case of 11 years' duration in a woman, aged 63 years, affecting the left second division of the fifth nerve—has had five months relief from her attacks of pain since I injected the left infra orbital nerve and the palatine foramina in October last This was followed by complete anæsthesia of the cheek and palate, with complete disappearance of the pain, which was so severe, and the attacks of which were so frequent, that she said she thought she "would have gone mad The attacks of pain were started by eating, talking, touching her nose or upper lip, or would come on spontaneously, especially at night During the last month the anæsthesia has been gradually lessening on the upper lip and cheek, and the attacks of pain are commencing to come on again, though not yet with such severity as formerly She has asked me to inject the nerve again, and this time I shall inject the superior maxillary nerve close to the foramen rotundum, in addition to again injecting the infra orbital nerve and the anterior palatine nerve By attacking the main trunk of the nerve close to the skull, as well as destroying it peripherally, the period required for regeneration of the nerve fibres, and the consequent relief from the attacks of pain, is likely to be longer, and I shall hope to obtain for her not less than six months', and possibly longer, freedom from return of the pain Of the remaining three cases, one was a case of three years' duration of spasms of pain affecting the right third division of the fifth nerve in a woman aged 78 years Early in December I injected 80 per cent alcohol around the foramen ovale, causing complete passing away of the pain In this case the injection was perineuritic, not into the substance of the inferior maxillary nerve Consequently, although a certain degree of numbness along the jaw was produced, there was no anæsthesia, and yet the attacks of pain completely subsided, although before the injection they were so severe and frequent that scarcely any food could be taken, and that only in a liquid form

Another case of epileptiform neuralgia, affecting the left second division of the fifth nerve, occurred in a woman, aged 40 years, who had suffered severely for six years I saw her in several of the attacks of pain, the most severe and intense that I have ever witnessed The slightest touch on the upper lip or side of the nose would start an attack, causing her to scream out, to clasp her hands to her head, and to moan and rock with the pain for about three quarters of a minute In such a case it appears to me, it would be more than brutal to attempt to inject without employing a general anæsthetic, though it is the practice of all the continental and American workers, following Schlosser, to use no anæsthetic Eight weeks ago under chloroform I injected the second division of the fifth nerve of this patient at the foramen rotundum with 15 minims of 80 per cent alcohol, and also injected a few minims into the infra orbital foramen The result was perfect there being complete loss of pain and inability to start it in any way by rubbing the skin of the face, blowing the nose, or any of the movements which formerly infallibly induced the attacks There was considerable œdema of the cheek and upper lip for three days, which then disappeared completely, though the anæsthesia of the area of skin and mucous membrane supplied by the superior maxillary nerve remained complete

Another case of trigeminal neuralgia affecting the first or ophthalmic division on the left side, in a woman, aged 54 years who had suffered from recurrent severe spasms of pain over the eyebrow for the past eight years, was completely relieved after two injections at the supra orbital notch mental foramen and under the skin of the outer portion of the eyebrow and forehead Although the pain was limited to the ophthalmic division of the nerve there was a sensitive area on the left side of the chin in front of the mental foramen, pressure on which, or sometimes even touching, would start the supra-orbital pain. At the first injection with alcohol I had overlooked the fact that there was an area on the outer part of the eyebrow which was very sensitive, though less so than the region of the supra-orbital notch, and it was not until the pain and sensitiveness of the supra-orbital region and the chin had passed away as the result of the first injection that I became aware of this painful area on the outer portion of the forehead, pain in which was started by rubbing the skin of the upper eyelid or the eyebrow. A second injection under the eyebrow and again of the supra-orbital nerve made this region also anæsthetic, and all the attacks of pain were completely subdued.

In addition to these cases of true trigeminal neuralgia, I have also treated three cases of severe recurrent supra-orbital neuralgia, post-influenzal in origin, with injection of alcohol and eucaine around the supra-orbital notch. In each case one injection has been sufficient to relieve the pain at once, causing anæsthesia of a patch of skin above the eyebrow. The characteristic of these post-influenzal supra-orbital neuralgias is their daily recurrence, usually starting about 10 o'clock in the morning, reaching their maximum intensity of pain after an hour or two, and dying away after 4 P.M. or 5 P.M. The pain is often intensely severe, though it differs from true trigeminal neuralgia in the long continuance of the attack, the spasms of pain in trigeminal neuralgia rarely lasting more than from one-half to three-quarters of a minute. If untreated, these post-influenzal supra-orbital neuralgias may recur daily for three weeks or longer. After the alcohol injection, although the pain is almost instantaneously relieved, a neuralgic attack may return about three hours later after the action of the eucaine has worn off. This is at once controlled by the administration of a dose of pyramidon and effervescing caffein citrate, and there is usually no further pain, though sometimes a second injection is required.

Pain in the face due to implication of the branches of the fifth nerve by cancer of the tongue or tonsil, or by growths at the base of the skull, may be relieved completely by deep injections of alcohol into the second or third division of the fifth nerve at the foramen rotundum or foramen ovale. I have thus completely relieved two such patients.

One patient was a man, aged about 46 years, who was suffering from a tumour at the base of the skull, probably involving the sphenoid bone. He became gradually blind from optic atrophy, and later developed paralysis of the left external rectus, and began to suffer violent pain in the face on both sides, with anæsthesia of the right cheek. The pain became almost unbearable, and as anti-syphilitic treatment did no good, I injected both infra-orbital foramina with 80 per cent. alcohol. This completely relieved his pain for the time, but later pain was felt along the left lower jaw, indicating the extension of the growth to involve the left inferior maxillary nerve. I therefore, under an anæsthetic, injected the left inferior maxillary nerve at the foramen ovale with alcohol, and the patient when last heard of had remained quite free from pain for several weeks.

The other case of inoperable carcinoma of the tongue was that of a patient who was sent to me from the surgical out-patients at St. Mary's Hospital because of the severe pain from which he was suffering in the left side of the tongue and jaw. Without using any anæsthetic, I injected the left inferior maxillary nerve at the foramen ovale with 80 per cent. alcohol, causing anæsthesia of the chin and complete loss of the severe pain.

Three cases of *clonic facial spasm* I have also cured by injection of alcohol around the exit of the facial nerve from the stylo-mastoid foramen. This causes slight paresis of the nerve, but brings about immediate cessation of the clonic spasms of the facial muscles. If the nerve is actually punctured and injected with the strong alcohol, complete facial paralysis will be produced, though this will be recovered from in two or three months.

Sciatica may be successfully treated by injections of strong alcohol, though I am quite convinced that the injections must be perineuritic, not into the substance of the nerve. I have proved that the injection of five minims of 80 per cent. alcohol into the median nerve causes paralysis of the flexors of the fingers and of the radial flexor of the wrist, followed by reaction of degeneration in these muscles, in addition to analgesia of the median distribution on the hand. Cases have also been published of paralysis of the leg following an alcohol injection into the nerve, and these, together with Finkelnburg's experimental work on the same point, completely disprove Schlösser's statement that he injects 15 minims or more into the sciatic nerve for sciatica, curing the pain without causing any paralysis. What he really does, no doubt, is to inject the alcohol around the sheath of the nerve, not into the nerve itself, and this perineuritic injection may be sufficient to relieve all pain, as indeed occurred in one of my cases of trigeminal neuralgia, affecting the right third division of the fifth nerve quoted above. Such a perineuritic injection of 80 per cent. alcohol I made recently in a case of sciatica of seven weeks' duration, bringing about immediate relief from the pain. The actual injection of the alcohol is somewhat painful, but the pain passes off after a few seconds. The actual insertion of the needle may be made practically painless by freezing the skin with ethyl chloride. The nerve lies at a depth of from two to three inches from the surface at the lower gluteal fold, which is generally the best point to choose for the injection. No general anæsthetic should be given owing to the danger of puncturing and injecting the nerve itself, and the patient's sensations will be the guide as to when the point of the needle reaches the sheath of the nerve, practically no pain being felt after the skin puncture until the sciatic nerve itself is reached. It is not always an easy matter to hit off the nerve, and those who imagine that they are treating sciatica by acupuncture of the nerve by thrusting from four to six needles into the nerve, are, I am sure, deluding themselves; most, if not all, of the needles do not hit the nerve at all, but pass to one side of it. I have proved this several times in the post-mortem room by attempting to inject the sciatic nerve at the lower gluteal fold with methylene blue and then dissecting down to my injection, and have found almost invariably that my injection has been to one side of the nerve, once as much as an inch and a half to one side However, the nerve may be hit, and therefore I think it necessary that no general anæsthetic should be used, as the point of the needle must feel for the nerve, and the patient's sensations of pain down the leg will be the guide when the sheath is reached.

Technique for trigeminal neuralgia.—In all cases of trigeminal neuralgia all tender spots, irritation of which gives rise to the pain, should be injected subcutaneously with several drops of the 80 per cent. alcohol. This is a comparatively simple procedure. Next, the various superficial foramina, such as the mental foramen for the third division, the infra-orbital foramen for the second division, and the supra-orbital notch if the ophthalmic division of the nerve is affected, should also be injected with a few drops of the alcohol. Of these the mental foramen is the most difficult to hit. Other foramina that may also be injected in suitable cases are the inferior dental, the palatine, the malar, and the anterior ethmoidal for the nasal branch of the first division. For the inferior dental a strong curved needle must be used and it may be reached either round the back of the ascending ramus of the mandible or from within the mouth.

Deep injections of the second division of the fifth nerve in the spheno-maxillary fossa at the foramen rotundum and of the inferior maxillary nerve at the foramen ovale require a great deal of practice. This must be acquired first upon an articulated skull and then in the post-mortem room. Many different articulated skulls should be studied in order to become familiar with the bony variations that are liable to be met with in the zygomatic fossa and in order to become acquainted with the varying depth of the foramina from the surface in different sized skulls. Although general directions can be given for reaching these two deep foramina, unless absolute familiarity with the base of the skull in this region is attained to the degree of being able to call up a mental picture of the parts, and thus recognise what the point of your needle is doing, frequent failure is sure to result and great damage may be done. In order to attain the certainty of placing my injection in the foramen ovale, or foramen rotundum, I have found it necessary to practise on a large number of articulated skulls and in over 60 bodies in the post-mortem room, using methylene blue for my injection in the latter, and tracing the course of the injection after taking out the brain. My methods are, roughly, as follows.

For the *foramen ovale* I use a moderately stout hollow needle, 1·2 millimetres in diameter, with a short point, without a stylet. This is pushed through the cheek below the zygoma, on a line joining the ala nasi with the incisura notch of the ear, and about 1¼ inches in front of this notch. If pushed in horizontally the point of the needle will sometimes strike the ramus of the mandible just below the sigmoid notch, but depressing the handle of the needle slightly will allow the point to slip through the lowest level of the sigmoid notch into the zygomatic fossa. Directing the needle slightly upwards and backwards the base of the skull will be reached at a depth of about 1¼ inches, the point of the needle striking the under surface of the great wing of the sphenoid. The handle of the needle must then be depressed and the point of the needle be made to slide along the bone until it engages in the foramen ovale, at a depth usually of 1½ inches. In some skulls the needle must be directed more upwards, as high as 30 degrees upwards, and in others it must be directed at the same angle backwards. If the needle is pushed in too horizontally the wall of the pharynx will be pierced at a depth of from 2 to 2¼ inches, or again, if it be pushed too far through the foramen ovale, the cavernous sinus and internal carotid artery will be punctured. To avoid this the needle should never be passed through the foramen to a greater depth than 2¼ inches from the surface, even in those cases where it is thought advisable to inject the ganglion itself. If the neuralgia is limited to the third division of the nerve it will be sufficient usually to inject the nerve itself at the level of the foramen, without passing the needle through into the ganglion. Brissaud and Sicard adopt the landmark of the posterior edge of the external pterygoid plate, which will be struck at a depth of about one and a half inches, and then feeling with the point to its upper and posterior edge, when the needle will slip back into the foramen which lies immediately behind it. They also sink the needle in nearer to the zygoma. This line has two disadvantages, as the direction of the needle must be altered after it has been sunk deeply, which is not always easy to do with the fine needle they use, and, more important, the needle is likely to be caught under the pterygo-spinous ligament, and thus prevented from reaching the foramen ovale at all. Sometimes this ligament is completely ossified by a bridge of bone joining the upper and back border of the external pterygoid plate to the spine of the sphenoid, forming a foramen which would be mistaken for the foramen ovale. Indeed, it is clear from their description of their method[1] that they have fallen into this error in at least one case. They recommend a fine platinum needle, of 0·7 millimetre diameter only. I do not find a fine needle nearly so satisfactory as a stouter one, though I do not consider it necessary to use such a stout one, with a stylet, as recommended by Schlösser, and adopted by most of his followers. I find that a fine needle bends so easily that it is quite impossible to be sure that the point of the needle is following the changes of direction given to the handle, and I do not find that the stouter needle causes any more vascular injury than does the fine needle. The internal maxillary artery turns into the zygomatic fossa at the level of the bottom of the lobe of the ear which is well below the bottom of the sigmoid notch, and the only branch liable to injury is the middle meningeal, and the needle should not be directed far enough backwards to damage this vessel.

The *foramen rotundum* is best reached by sinking the needle below the malar bone in front of the coronoid process slightly in front of a line prolonging the posterior border of the orbital process of the malar across the zygoma. The needle should be sunk inwards, backwards, and upwards at an angle of about 40 degrees upwards and 30 degrees backwards. The needle will then strike the anterior border of the external pterygoid plate at a depth of about 1¾ inches, and the point of the [illegible] forwards so as to sl[illegible] this plate through t[illegible] spheno-maxillary foss[illegible] angle upwards the p[illegible] nerve at its point of exit from the foramen rotundum at a depth of about two inches from the surface, though in the small skull of a woman of the height of 5 feet 2 inches the foramen rotundum will be reached at a depth of only 1¾ inches. It is most important to remember the depth at which the foramen lies as it is not always possible to make the point of the needle engage in the foramen owing to the backward projection of the antrum in some skulls narrowing the pterygo-maxillary fissure to such a degree that the needle passes in front of the foramen and cannot be made to pass into its anterior lip. If the needle be pushed farther in the same line for three-eighths of an inch the optic nerve will be struck at the optic foramen, and in some skulls it is possible to push the needle straight through the sphenoidal fissure into the brain. When injecting the superior maxillary nerve, therefore, the needle must never be sunk to a greater depth than 2¼ inches from the skin for a large skull, as of a man of 6 feet in height, or more than 1¾ inches for a small skull of a woman of 5 feet in height. If the needle cannot be felt to engage in the foramen rotundum the injection must be made at the required depth, and it is then always perineuritic, the nerve trunk not being actually pierced. Fifteen minims of the strong alcohol slowly injected is perfectly safe from injuring the optic nerve or the third nerve if the precautions as to depth are observed.

Schlösser, Brissaud and Sicard, and all the other users of this method whose writings I have perused use no general anæsthetic, principally for the reason that the patient is able to inform them by a scream of pain when their needle reaches the ner[illegible] ia especially I prefer t[illegible] anæsthesia, as thereby [illegible] ured, and I am not conscious of being hurried, and can therefore perform the injection far better. If the bony anatomy of the parts is thoroughly familiar, as I have already urged to be absolutely necessary, it will be unnecessary to require the information from the patient as to when the nerve is reached, though this sign may be also secured by allowing the patient to come round partially from the anæsthetic after the needle has been inserted and the point is ready to strike the nerve. The patient will then be seen to give a twitch of the face as though in pain, though afterwards no memory of the pain remains.

It is almost needless to remark that the strictest aseptic precautions are necessary. Some advise keeping their needles in absolute alcohol, but I always boil my needles in 1 per cent. bicarbonate of potassium in distilled water immediately before use. The skin is sterilised with ether soap and is then rubbed with a little lysol, which is mopped off with absolute alcohol. The puncture wound is sealed with a small collodion dressing, which may be taken off after the third day.

A certain amount of œdema of the face is constant after alcohol injections, but this is of no consequence and it passes off after two or three days. Hæmatomata sometimes result from puncture of an arterial branch, but I have only encountered this once, when puncture of the infra-orbital foramen when injecting the infra-orbital nerve caused a slight hæmatoma of the lower eyelid and adjacent skin of the cheek.

In conclusion, I am of opinion that this method is a certain relief for trigeminal neuralgia, and though recurrence of the pain is likely after an interval, varying from four or five months to as long as 18 months, it is perfectly simple to repeat the injection whenever necessary. This appears to me far preferable to the more serious operation of extirpation of the Gasserian ganglion, and certainly should at all events be tried first.

In addi[illegible] method is of great service i[illegible] n, and also other forms of [illegible] supra-orbital neuralgia, the facial pain of [illegible] or jaw, and in chronic sci[illegible] the lower limbs and other causes of severe persistent neuralgia below the mid-dorsal region I consider may possibly be also relieved by this method, by injecting the spinal nerves at their point of emergence at the intervertebral foramina. These foramina I have found comparatively easy to reach for the lower dorsal, lumbar and upper sacral roots.

A SIMPLE OPERATION FOR THE COMPLETE REMOVAL OF TONSILS, WITH NOTES ON 900 CASES.

BY GEORGE E. WAUGH, M.D., B.S. LOND., F.R.C.S. ENG.,

SENIOR SURGEON TO OUT-PATIENTS AT THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, W.C.

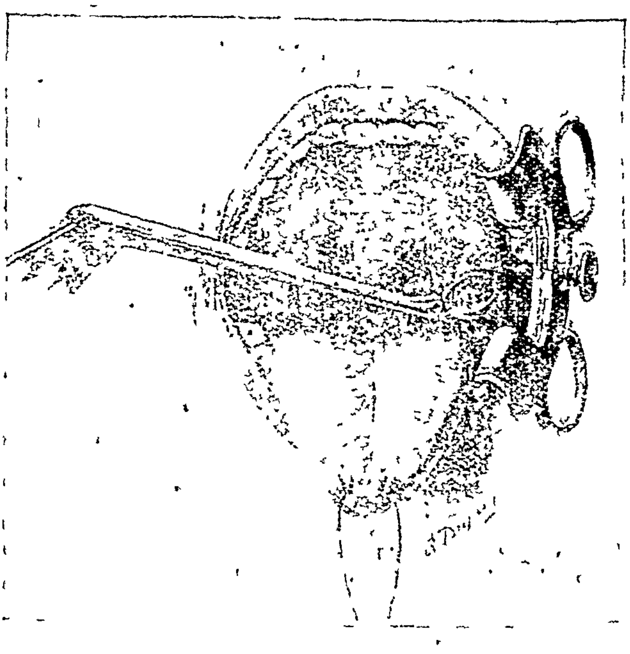
IT has long been recognised that the tonsil resembles in mode of development[1] and structure an ordinary lymphatic gland. That further, as the result of disease, it undergoes changes which are identical with those occurring in lymphatic glands in other parts of the body under similar morbid conditions. Nevertheless, the treatment of these conditions—except of such rare ones as invasion by malignant neoplasms—has not been carried out upon those surgical principles which govern the treatment of diseased lymphatic glands in other regions. The reasons alleged by writers upon the subject are generally either that that form of treatment which violates those principles—i.e., tonsillotomy—is quite satisfactory, or that that form of treatment which implies adherence to those principles—i.e., tonsillectomy—is too difficult.[2] Neither of these reasons appears to me to be valid. The failure of tonsillotomy by other operators to afford relief from the symptoms for which it was performed in 143 out of the 900 cases here recorded and the designing of a simple and safe form of tonsillectomy, to be described later, appear to support this conclusion.

It is probably a common experience of all large out-patient departments—and certainly of my own at Great Ormond-street—to find a large number of patients upon whom tonsillotomy has been performed and to whom no relief either of the local or general condition for which the operation was done has resulted. From the frequency with which the operation has been repeated—sometimes as often as three times, and from the fact that the operation has been performed by many operators at other hospitals in these 143 cases, it seems right to conclude that the cause of failure lies not with the operator but with the type of operation. Even in highly skilled and experienced hands the complete removal of a tonsil by means of the guillotine is a task of such mechanical difficulty as to be, except in a few rare cases, quite impossible.

The cause of failure to afford relief in these cases already alluded to is the persistence of the remains of septic tonsillar tissue of such a size as to be quite inaccessible to the guillotine. This further emphasises the fact that it is not primarily *the size* of the tonsil which matters, but *the septicity*, and this may be of a high degree in a comparatively small tonsil. By virtue of its situation, at the upper end of the alimentary tract, a diseased tonsil can pour septic contents from its cryptic surface continuously into the alimentary canal at the same time as absorption can occur through its lymphatics into the adjacent glands in the neck. It thus has a two-fold power of doing harm. The danger of continually swallowing septic matter from carious teeth has long been recognised, but the similar danger of continually swallowing septic material from decaying tonsils has not been sufficiently emphasised. This attitude of indifference has largely arisen from regarding the removal of tonsils as being only necessary when it is possible to slip them through the ring of a guillotine. Hence the potency of the small imbedded septic tonsil to do harm[3] is easily overlooked, and more especially in children who seldom complain of a "sore-throat," even when the tonsils are inflamed. Provided that the tonsils give rise mechanically to obstruction to swallowing or breathing on account of their size, or the patient suffers from frequent attacks of sore-throat, or has enlarged glands in the neck or intractable middle-ear disease, the cause of the trouble is promptly recognised. But there is a large group of cases which is characterised by none of these troubles, and is made up of children who are simply profoundly debilitated, poorly nourished, exhibiting lassitude both in work and play, and who are frequently described as being victims of a "weak constitution."[4] Of such a type are 126 of the cases here recorded. Sometimes there is direct evidence of disorder of the alimentary tract, such as pain and vomiting after food, obstinate constipation, or frequent attacks of offensive diarrhœa. It is not to be supposed, however, that these groups of symptoms are to be explained solely by the presence of diseased tonsillar tissue. They are merely evidence of chronic toxæmia, and in searching for the primary focus of infection the small imbedded irregular tonsil must not be overlooked. And even when this type of tonsil has been present—as it was in the 126 of the cases recorded and which presented these groups of symptoms—it was not considered justifiable to remove them until a physician had satisfied himself that no other cause for the illness could be detected. (Most of these 126 cases were under the care of my colleague, Dr. R. Hutchison, to whom I am indebted for permission to refer to his notes upon them.) That it was the main cause in a very large number of cases was indicated by the results following complete removal.

The objection to "tonsillectomy" on account of the difficulty of the operation has been overcome by the following operative procedure, which has already stood the test of application to over 900 cases.

FIG. 1.



Showing imbedded tonsil with free surface level with the pillar of the fauces grasped by conchotome.

The instruments required are two Hartmann's ring conchotomes (Hett's modification has added a useful serration to the margin of the lower ring), one pair of curved scissors, and one pair of fine-toothed dissecting forceps. The patient must be prepared by a preliminary visit to the dentist, so that no operation in the oral cavity is performed until all carious teeth have been stopped or removed. The patient is placed in a recumbent position with a sandbag beneath the shoulders, with the head falling slightly backwards, so that the naso-pharynx slopes backwards and downwards, thus enabling the small quantity of blood which is shed to trickle towards the nostrils rather than towards the larynx, whilst the slope is not so great as to cause engorgement of the pharyngeal venous plexus. A loop of silk is passed through the tip of the tongue for the purpose of retraction, and a gag is inserted between the last molar teeth. The tonsil is then seized in one of the pairs of ring

---

[1] I am indebted to Mr. G. S. Hett, having read his paper published in THE LANCET of Feb. 13th, 1909, in which he describes the development of the tonsil.

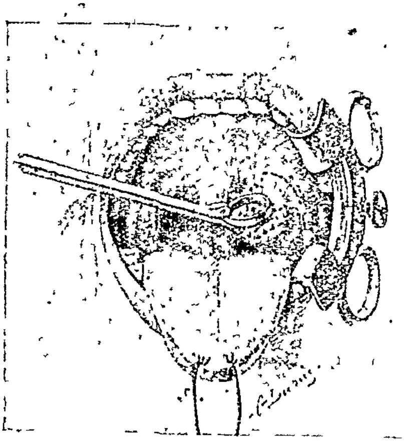
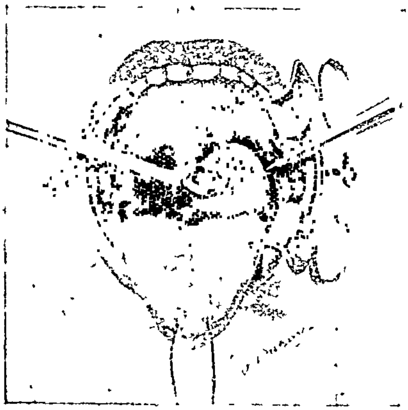
[illegible] middle line, so that the [illegible]neath its normal cover- [illegible] (Fig. 1.) Immediately [illegible] he anterior pillar, just where it blends with the surface of the tonsil, an incision is made with the fine-toothed forceps, parallel to and extending for the whole length of the free margin of the anterior pillar. (Fig. 2.) This incision reveals the capsule of the tonsil which now appears as a glistening smooth bluish-white surface. (Fig. 3.) (The ease and success of the operation depend upon this incision displaying the capsule of the tonsil and not entering its substance. This mistake is easily made by keeping too near to the free surface of the tonsil, and it is the common cause of difficulty and failure for beginners.) The ring forceps is then readjusted so as to get a firm hold upon the tonsil and the anterior pillar is drawn outwards by means of the fine toothed forceps. The tonsil is then practically dislocated from its bed, and the separation of the rest of the layer of fine cellular tissue, intervening between the capsule of the tonsil and the muscular wall of the pharynx, is easily effected either by the fine toothed forceps or by a closed pair of curved blunt-ended scissors which fit in behind the whole of the tonsil and push the pharyngeal wall away from it. (Fig. 3.) Since the tonsillar vessels are thereby torn across and are able to retract within the muscular wall of the pharynx, there is practically no bleeding—in fact, the absence of bleeding forms a striking contrast to the sharp hæmorrhage which ensues after the tonsil has been cut across by a guillotine.

FIG. 2.



Tonsil drawn inwards and incision made along dotted line This line is close to the free margin of the anterior pillar of the fauces, which does not appear owing to the bulging of the imbedded portion of the tonsil during traction.

FIG. 3.



A[illegible] drawn outwards and tonsil [illegible]

The time occupied in the complete removal of both tonsils and adenoids is, on an average, three minutes A brief deep anæsthesia with chloroform is necessary, and the coughing reflex should be abolished. If it is present it adds a distinct danger to the operation, since coughing enormously increases the hæmorrhage, and during the ensuing inspiration blood could easily be sucked into the larynx. Under the conditions detailed above the [illegible] During the operation tra[illegible] fauces must be avoided, [illegible] spasm of the glottis.

For the after-treatment a simple mouth-wash is provided and a mixture containing salicylate of soda and chlorate of potash, administered every few hours. The patients are kept in bed for about 48 hours and are allowed solid food when they feel inclined for it With children this is frequently on the day after the operation.

All the above 900 cases have been seen at the end of a week and at *the end of five weeks from the date of operation.* Their ages range from six weeks to 41 years. There have been no complications, such as hæmorrhage or sepsis As a rule the temperature seldom reaches 100° F. after the operation. Of the 126 cases who had been chiefly under the care of Dr. Hutchison, suffering from general debility, 12 showed no improvement after the operation. In the remainder of the cases rapid and complete recovery was made. Of those suffering only from throat symptoms 774 cases have been operated upon Of these 143 had already had their tonsils "guillotined"—some of them as often as two or three times —at other hospitals with no relief to them. They all made an uninterrupted recovery. A typical case from this group may be quoted.

The patient, aged nine years, had his tonsils guillotined at a London throat hospital in November, 1906, on account of sore throat. He continued to suffer from this affection until March, 1907, when he contracted scarlet fever. Since then, the attacks of sore throat had become more frequent. On examination, large imbedded masses of tonsillar material were seen to be present Since the removal of these by dissection in July, 1907, he has remained quite well.[5]

Welbeck-street, W

A RARE CARDIAC CONDITION: MITRAL STENOSIS WITH BALL-THROMBUS IN LEFT AURICLE.

BY ALEX MILLS KENNEDY, M.B., CH.B. GLASG.,
ASSISTANT PATHOLOGIST TO THE GLASGOW ROYAL INFIRMARY.

IN cas[illegible] to find ante-mortem [illegible]icle, but such a curiou[illegible] called ball-thrombu[illegible]nt its occurrence being placed on record.

The case was that of a well-developed and well-nourished woman, 47 years of age, who was admitted to the Glasgow Royal Infirma[illegible] action of the [illegible] systolic and [illegible] the apex. The second pulmonic sound was reduplicated. Four years ago the patient had been treated in this hospital for her cardiac condition. At that time a presystolic murmur at the apex was made out. It is 12 years ago since the from the parasite, though I cannot recommend them any sovereign remedy, I can truly bid them not to be disheartened. Their condition is not such as they have been led to believe, and each day that they protect themselves from invasion brings them nearer the time in which they will almost forget that they were ever affected by the bilharzia hæmatobia.

RUPTURE OF THE PREGNANT UTERUS FROM CONTRECOUP IN A WOMAN NOT IN LABOUR; OPERATION; RECOVERY.

BY JOHN PHILLIPS, M.A., M.D. CANTAB., F.R.C.P. LOND.,

PROFESSOR OF OBSTETRIC MEDICINE AND GYNÆCOLOGY IN KING'S COLLEGE; OBSTETRIC PHYSICIAN AND GYNÆCOLOGIST, KING'S COLLEGE HOSPITAL; EXAMINER IN MIDWIFERY, LONDON UNIVERSITY AND THE CONJOINT BOARD.

THE following case appeared to me of sufficient interest both from the rarity of the accident and the concomitant symptoms to warrant publication.

On March 8th, 1908, the patient, a healthy VI.-para, when seven months advanced in pregnancy, fell from a first-floor window, from 12 to 14 feet high, on to her buttocks; she remembered striking on an oaken edging to the garden path. She was seen by Dr. P. N. Randall of Bromley (to whom I am much indebted for the following notes) about an hour and a half after the accident. Her pulse was fairly good; she was conscious, but in great pain in the right side of her abdomen. Fœtal movements had been felt immediately after the accident but not since. There was no definite paralysis of the legs but she was unable to move them in any way and it was necessary to draw off the urine by catheter twice daily for the 16 days subsequent to the accident. Three days after the accident (the 11th) she developed acute bronchitis, and eight days after (on the 16th) a little blood escaped from the vagina for the first time and gradually became more free.

The patient was seen in consultation on March 18th, ten days after the accident. She was a spare brunette and looked ill; her respirations seemed quicker than normal, and her pulse was feeble (104). There were loose râles heard over both lungs. On inspection of the abdomen it presented none of the features of a seven months fœtation, and coils of intestines were very distinctly seen through the thin abdominal walls. There was no distension and no tenderness on pressure. No fœtal heart sounds could be heard, but a distinct uterine souffle could be made out to the left of the median line in the lower hypogastrium. The areolæ were stained but the breasts were not active. On palpation of the abdomen there was an absence of the usual uterine tumour halfway between the navel and the epigastric notch. Extending from the lower edge of the liver to the right inguinal region there was an irregular, somewhat ill-defined swelling made out. Some prominences were noticeable upon its surface. A fœtus could be palpated with its face looking to the left. In the lower hypogastrium and in the median line could be felt a soft, elastic, globular swelling, reaching halfway between the symphysis and the navel; this gave the sensation to the touch of a uterus recently emptied of its afterbirth, or the uterus of a far-advanced extra-uterine pregnancy. Per vaginam, a slight mucous discharge with a little bloodstain mixed with it was going on; the cervix was soft and admitted the finger to the internal os uteri. The swelling felt in the lower hypogastrium was clearly the uterus; the mass in the right groin could not be clearly defined; the left loin and fornix appeared to be quite free and healthy. Extending from the uterus, across to the swelling in the right loin, was an indefinite mass which appeared to have a slight amount of restraining action on the mobility of the uterus.

It was considered that the case might be: (1) one of ruptured uterus with the fœtus lying among the intestines on the right side; (2) the possibility of a primary abdominal extra-uterine fœtation; or (3) pregnancy in a bi-cornuate uterus. It was considered that the case would possibly be elucidated by the passage of the sound; this was found to pass easily into the uterus and considerably beyond the fundus; its point could be felt immediately behind the thin abdominal wall about three inches above the umbilicus; it appeared to pass in front of the fundus uteri.

The patient was anæsthetised and the finger inserted into the cervix. After a little upward pressure, about two inches above the internal os uteri, a ragged, longitudinal opening was felt and a lobe of separated placenta impacted in it; no liquor amnii or fœtal parts could be made out *in utero*, but in the right inguinal region what appeared to be a leg could be palpated by the finger in the uterine cavity, showing clearly that it was outside the uterine wall. Diagnosis was therefore made of ruptured uterus, probably of the anterior wall, the dead fœtus lying in the right side of the abdomen. The abdomen was opened in the median line. On reaching the subperitoneal fat it was found to be yellow and parchment-like, and the peritoneum itself very soft and breaking down on touching. On opening the cavity a considerable amount of dark blood-stained fluid escaped and the uterus was seen immediately beneath the incision. An irregular longitudinal opening, with retracted edges, was noted at the lower end of the incision wound; on the right a female fœtus with the skin macerated was seen lying among the intestines; the great omentum was deeply stained a brown colour. On passing the hand into the peritoneal cavity the fœtus was felt lying on its left side, with the head in the epigastrium, the face towards the anterior abdominal wall, its right shoulder under the liver, and the buttocks and legs in the right iliac fossa, the head being somewhat moulded by the cleft in the liver. The placenta was lying across the front of the uterus, a small portion of it occupying the laceration already spoken of in the anterior wall of the uterus; this was obviously what was felt interfering with the mobility of the uterus. It was quickly removed, the uterine cavity carefully explored, and some small pieces of adherent placenta removed. The fœtus was lifted out through the abdominal wound, some large blood-clots were taken out with sponges, and the uterus, in a fairly good state of contraction and retraction, was brought to the surface. The sloughing edges of the uterine wound were pared carefully and brought together by two layers of superimposed silk stitches. The parietal peritoneum was then stitched to the sides of the uterine scar (abdominal suspension) and gauze drainage was applied. The abdominal wound was then closed. During the operation nearly three pints of saline fluid were injected into the cellular tissues of both breasts and the peritoneal cavity. The condition of the patient at the end of the operation was fairly satisfactory and she was got back to bed, with a pulse of 110 per minute, of a feeble but regular character. The fœtus showed no abnormalities of development; it weighed 3 pounds 13 ounces and the skin was peeling.

The post-operative history was uneventful. The bronchitis slowly cleared up, the patient's temperature remained below 100° F., and her pulse gradually descended to normal. I saw her again on Jan. 13th last (about ten months after the operation). I then found the scar quite healthy, the uterus a little bulky but freely mobile, anteflexed and anteverted, and the patient's only complaint was that whereas before the accident she had had painless menstruation she now suffered from colicky pains in the lower hypogastrium during the whole time of the flow.

A few points in the history of this case seem worthy of attention. It may be noted that a woman with a ruptured uterus for 10 days, the fœtus, blood, liquor amnii, and the larger portion of the placenta lying in the peritoneal cavity, showed no indications of acute peritonitis or any general symptoms of importance. It is possible that the impaction of the soft placenta in the longitudinal rent in the anterior wall may have in some way prevented the entry of germs into the peritoneal cavity and so saved the patient an acute illness as well as have arrested hæmorrhage. The position of the rent was an unusual one and must have been caused by the reflected impact of the child's body against the anterior uterine wall. I have been unable among more recent literature on the subject to find any case of a similar nature. The ventro-suspension was not in itself necessary, but it was thought desirable to cut off the laceration from the general peritoneal cavity. The dysmenorrhœa is probably due to interference with the bipolar action of the uterus during menstruation.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

Exhibition of Cases.—Acute Infective Gangrene of the Extremities.

A MEETING of this section was held on April 30th, Dr. A. E. GARROD being in the chair.

Dr. G. A. SUTHERLAND showed three Mongolian Imbeciles. The first was a boy, aged five years and nine months, with the following characteristics: small head, small palpebral fissure with the axis sloping inwards and downwards, depressed bridge of the nose and epicanthus, the openings of the nares directed upwards, the mouth wide open, the tongue large with some transverse fissuring, horizontal nystagmus and head-shaking, and little finger and thumb shortened, with slight curving of the former. Nasal obstruction was pronounced until operation for adenoids was done. *The boy was very imitative, active, and required* constant supervision. His habits were clean. Mental development was progressing but was still very backward. *The second was a female patient, aged six years.* She was active, imitative, and fond of music, required constant supervision, and could not form sentences yet. Her mental development was progressing slowly. The third was a boy, aged four years, who could say simple words and learned to walk at the age of two and a half years. The left hand shows shortening of the thumb and complete webbing of the third, fourth, and fifth digits. He was very fond of music and imitative and active in his habits. His mental development progressed very slowly. Dr. Sutherland said that he did not think any light would be thrown on the condition of Mongolian imbecility until they knew the cause of the disease. Treatment by thyroid was not successful and if a *case improved under that treatment in all probability it was* not a case of Mongolism. Prognosis of life in these cases was bad, most of them dying under two years of age.

Dr. H. MORLEY FLETCHER showed three cases of Mongolism, two of the cases being five years of age, the third 6½ years of age. He pointed out that the skin of the hand in such cases showed a certain peculiar roughness or harshness.

Dr. F. J. POYNTON showed four Mongolian Imbeciles. The first was a girl, aged four years. She was brought to Great Ormond-street Hospital when aged six months, and since then—namely, for three and a half years—had been treated with small repeated doses of thyroid. She talked when aged two years and ten months. *She was passionate,* fairly clean, and could say a few words, and was fond of musical sounds. The second was a boy, aged nine years. He had always been noticed to be backward. He took the bottle until three years of age, and for many months, instead of [illegible] it in tailor fashion, [illegible] years of age. He [illegible] since September, 1908, with small doses of thyroid. The degree of intelligence was small; he could not talk consecutively, nor read, nor learn, but he could take a simple message. He was usually clean and could amuse himself. Since thyroid treatment was started friends and relations considered him "brighter," but it was difficult to discover any real improvement. The third was a female, aged three years, who had been treated for over a year with thyroid and during that time had made progress She commenced to walk when aged two and a quarter years and could now make a certain amount of progress on her feet. The general aspect was of the usual type. The child was fond of musical sounds and understood, though slowly, a good deal that was said to her. She was unable to talk but was now beginning to make efforts. The fourth was a female, aged four years, who had been treated since the age of ten months with small continuous doses of thyroid. This characteristic Mongolian imbecile was now beginning to talk and was fairly clean. She did not appear to have made any real advance over other cases which had not had any thyroid treatment. Dr. Poynton said that the object of showing the group of cases was to raise the point as to the value, if any, of thyroid treatment in the condition of Mongolian deficiency. His four cases were in themselves of the usual type, the oldest being of a comparatively mild degree. They were not related to one another. 12 cases had been treated for prolonged periods with thyroid, but the results had not been encouraging. Poor circulation and severe chilblains were somewhat improved by this remedy, and it would appear that these cases were rather brighter and more responsive after commencing the treatment. There did not seem to be any specific action on the underlying constitutional deficiency. In his experience considerable doses of thyroid soon induced in Mongolian imbeciles signs of excitement and disturbance of health as a direct result, and for that reason small doses *only had been given for prolonged periods, such, for example,* as one grain of the powdered gland twice a day for a child aged three years. In his series of cases some had been first born, some last born, and others in the middle of a family. Some mothers had been young, some old, and some neither young nor old.

Dr. F. S. LANGMEAD showed Two Mongolian Imbeciles. The first was a boy, aged one year and seven months, with congenital morbus cordis, as evidenced by a loud systolic bruit, and an accessory auricle on the right side. The second *was a girl, aged three years. At two years of age she could* just sit and crawl and now was beginning to walk with help. There was a congenital lesion of the heart, as shown by an *increase of the cardiac dulness to the right, and an evident,* but slight, murmur in the pulmonary area.

Dr. LEONARD GUTHRIE showed Two Mongolian Imbeciles. One was a fat, sturdy boy, aged five years, of typical Mongolian aspect. He had extraordinary powers of imitation, [illegible] manners. The other was a boy, aged eight years, with signs of cretinism that had improved under thyroid treatment. Dr. Guthrie considered that thyroid treatment was absolutely *useless in the ordinary cases of Mongolism unless the patient* also exhibited signs of cretinism.—Dr. G. E. SHUTTLEWORTH said that thyroid treatment did not improve patients suffering from Mongolism. In the better-class patients treated in favourable circumstances the results of careful training were not so discouraging as was generally thought. It was, however, by imitation that these patients succeeded in accomplishing any work, and the period arrived when imitation could not carry them further in the active work of the world, through lack of originality and initiation. With regard to the mortality in this disease, the patients were exceedingly prone to die from tubercle and comparatively few lived to the age of puberty.

Mr. J. JACKSON CLARKE showed six cases of Successful Treatment of the Congenital Dislocation of the Hip by the Manipulative Method, and Mr. V. WARREN LOW also showed a similar successful case.

Mr. JAMES SHERREN showed a case six years after the performance of Omentopexy for Ascites due to Cirrhosis of the Liver. The patient was a woman, aged 34 years, who was admitted into the London Hospital in April, 1903. Her abdomen was then distended with fluid, the liver could just be felt below the costal margin, and the spleen was markedly enlarged, reaching nearly to the umbilicus. There had not been any hæmatemesis or melæna, and she was not jaundiced. At the operation on April 28th, 1903, the abdomen was found to be filled with clear yellow fluid. The liver was firm and typical of the type of cirrhosis known as "alcoholic." The wound healed by first intention, and she left hospital free from ascites and feeling well on May 27th, 1903 She had been seen on several occasions since and had remained free from symptoms. Two years after operation she bore a healthy child. The splenic enlargement had gradually diminished.—Mr. C. GORDON WATSON said that he had seen many patients operated on for ascites due to cirrhosis of the liver, but in the majority of cases the result was a complete failure.—Dr. H. D. ROLLESTON pointed out that the operation should be performed when the patient was in good condition as regards nutrition, and it was only occasionally that they came across cases suitable for this treatment.

Mr. E ARCHIBALD SMITH showed a case of Multiple Congenital Deformities in a boy two months old.

Dr. H. G. TURNEY showed a case of Trophœdema following Trauma. The patient was a male, aged 18 years. Six months ago he ran a nail into the inner border of his right foot and had not been able to work since. The slight injury soon healed, but ever since the accident the foot had been increased in size. The present condition was one of œdema of the right foot, which stopped abruptly at the ankle. The colour was normal, the skin was dry and coarse, and the nails were thickened. Movements were free and not painful. There was some general blunting of all forms of sensation (but particularly that of pain), not only over the foot but nearly up to the knee. The x ray examination was negative.

Dr. T. D. SAVILL and Dr. PHILIP GREEN showed a case of Sclerodermia associated with Angioneurotic Œdema. The patient was a female, aged 56 years. The skin of the hands, nose, forearms, and to some extent of the toes, was thickened and livid. There was no pitting on pressure. She could not use her hands to button her garments because of the mechanical difficulty of flexing and extending the joints. In the forearms the parts were becoming hide-bound owing to the thickening of the skin and subcutaneous tissue. Over the left clavicle was an area about 4 inches by 2 inches of smooth, shiny, thinned skin, such as that left by morphœa. The patient enjoyed fairly good health but had within the last few weeks developed a stiffness of the knee-joints having the characters of so-called rheumatism. She had had bilious attacks, starting in the early thirties, about once a week. Alternating with these she had attacks of swelling on various parts of the surface of the body. Both the bilious attacks and the swellings ceased about two years ago, at the age of 54 years, when the hands first began to be persistently affected. The cutaneous swellings had all the characters of angioneurotic œdema, sometimes preventing her swallowing and giving her an alarming feeling of suffocation. Her mother died at the age of 54 years from a sudden swelling of the face spreading to the throat and causing death within 24 hours. A daughter, aged 22 years, had had swellings in many different parts of the skin since the age of 12 years.

Mr. GORDON WATSON showed a case of Double Infantile Coxa Vara treated by subtrochanteric osteotomy. The patient was a girl, then aged 15 years, who was admitted to the Metropolitan Hospital in December, 1907, with a history of deformity of the hips and difficulty in walking since early childhood. She had then a waddling gait, lordosis, and swung the body from side to side like a case of congenital dislocation. The great trochanters were greatly elevated. Abduction was practically abolished but other movements at the hips were free, though limited. In dorsal decubitus the internal malleoli could only be separated 11 inches. At the present time, 16 months after operation, the legs could be abducted so that there was a distance of 36 inches between the malleoli and she walked well without waddling.

Mr. H. B. ROBINSON and Mr. W. H. BOWEN showed a case of Hereditary Transmission of Claw Hand and Foot in mother and child. The patient was a boy, aged one year, showing inherited claw-foot. His mother had a similar deformity of her feet and in addition had deformed hands. The child's grandmother and great-grandmother had similar deformities of the feet. A skiagram of the left foot showed the absence of the second metatarsal bone save for its proximal end. The cleft in the foot corresponded to the bony deficiency. The phalanges of the first metatarsal bone were present; those of the third and fourth bones were absent; and those of the fifth metatarsal bone were present, but the distal one of the two was turned outwards at right angles. The condition of the right foot was somewhat similar. On the right side the great toe tended to point in an outward direction. In some of the cases of the deformity this outward deviation of the great toe was very pronounced, and tended to meet the inwardly deflected little toe and produce the characteristic claw-foot.

Dr. A. M. GOSSAGE showed a case of Coarctation of the Aorta. The patient was a male, aged 16 years, who had always been rather short of breath, but had enjoyed fair health up to last October when he was attacked with right facial paralysis from which he had since partially recovered. On examination there was some serious dyspnœa and marked pulsation of the carotids. The heart was hypertrophied; the radial pulse was large with a sudden rise. There was pulsation in the second right interspace near the sternum where there was dulness on percussion. The superficial cardiac dulness reached the fourth rib and the right edge of the sternum. Systolic and diastolic murmurs could be heard over the aorta. Pulsation could not be felt in the abdominal aorta, iliacs, or femorals. There was a small artery passing down on the right side of the epigastrium from the lower ribs to the umbilicus, and a small artery could also be felt in each axilla, coursing down the sides of the thorax. Numerous small arteries passed at the back from the spine in the direction of the intercostal spaces under the skin. The aortic lesion was evidently congenital and was probably in the usual position just above the junction of the ductus arteriosus with the aorta.

Mr. W. FEDDE FEDDEN read a paper on six cases of Acute Infective Gangrene of the Extremities. He considered that infective gangrene might be produced by a great variety of definite organisms—namely, the bacillus aerogenes capsulatus, bacillus coli, bacillus pyocyaneus, *vide* Dudgeon and Sargent, streptococcus pyogenes, and staphylococcus aureus. It was a noteworthy fact that the bacillus of malignant œdema did not find a place in any of the six cases. The prognosis of cases due to bacillus aerogenes capsulatus was undoubtedly very much more favourable than in those due to streptococcal infections, whilst those due to staphylococci appeared to hold an intermediate position. The period between infection and the appearance of actual gangrene in the first group was almost constant—namely, from 30 to 36 hours—whereas in the group caused by streptococcus that period might be as short as an hour. The incubation period of the staphylococcal group was very variable, but might be prolonged to several days. The importance of early amputation was self-evident, and was so urgent that the diagnosis must be made on clinical data, as the time for bacteriological confirmation could not be afforded.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Exhibition of Cases.—Meningitis associated with the Leptothrix Bacillus.—School Life and Children's Vision.

A MEETING of this section was held on April 23rd, Mr. R. CLEMENT LUCAS being in the chair.

Mr. HUGH LETT showed: 1. Cystic Hygromata in a girl, aged 15 months, under the right arm, on the right elbow, and over the right scapula. The mass in the axilla was soft with irregular nodular areas. The skin over it was adherent and dimpled. There were no dilated veins or pulsation. 2. Multiple Masses under the Skin of the Thigh. The patient was a girl, aged six months. The swellings had been noticed since birth. On seeing the case three weeks ago the appearances had suggested lipomata, but one of the masses had now become softened and discoloured and there was phlyctenular ulceration of the cornea. The condition was therefore one of multiple tuberculous abscesses. 3. A Tumour of the Femur in a boy, aged 15 years. He had noticed a lump in the right thigh four years ago which had been growing slowly since. It causes the patient a little pain when the weather is damp. The urine contains a trace of albumin. 4. A case of Multiple Osteomata in a boy, aged four and a half years. He appeared to be normal until the age of 18 months, when his mother noticed lumps on his legs. Osteomata can be seen or felt at the ends of both tibiæ and humeri, at the adductor tubercles of the femora, on the vertebral borders and spines of the scapulæ, at the outer end of the right clavicle, on the ribs at the junctions of the cartilages and bone, and symmetrical nodes on the skull. The boy was well except that he got tired very quickly. The tumours were roughly symmetrical.—Mr. LUCAS said he had but little doubt that the three small swellings in Case 2 were tuberculous skin abscesses. The fact that one had become discoloured since Mr. Lett saw it three weeks ago indicated the probable contents of the others—namely, sweet white pus. With regard to the tumour on the thigh, he thought that it was an ossifying enchondroma, usually known as exostosis. The photograph showed that the bony part was growing, and as it was single he would be inclined to remove it.

Mr. R. WARREN showed a specimen from a case of Congenital Stenosis of the Rectum, Colon, and part of the Ileum. The baby was three days old and had passed no motion since birth. The finger could be passed one to two

inc
bó
aw
bh
nó
syringe. [illegible]

[illegible] anosis was increased. [illegible] the cubic millimetre of blood. The child died at six and a half weeks. The foramen ovale was not completely closed, admitting the passage of a pencil five millimetres in diameter. The ductus measured 15 millimetres in length and its channel was about five millimetres in diameter, being a little wider at its aortic end; the aorta was very slightly constricted where joined by the ductus. The lungs showed atelectatic patches in the upper lobes. The liver was slightly enlarged.—Dr. E. CAUTLEY asked Dr. WEBER whether he ascribed the cyanosis to the patent ductus or to the condition of the lungs. He thought himself that it was not due to patent ductus, because if there were mixing of the bloods there would be an excessive number of red cells which was not the case.—Dr. WEBER thought that the atelectatic patches had a share in producing the clinical condition.

Dr. A. J. JEX-BLAKE showed a case of Extreme Deformity of the [illegible] Lung. The patient had alw [illegible] a history of consumption on [illegible] At the age [illegible] onia and [illegible] abscess [illegible] ate with [illegible] Three [illegible] nd dull [illegible] ubbing. [illegible] from a sinus close to the sternum. Two further operations had been done. He had had a chronic discharge on and off [illegible] bronchitis on admission, but at the present time was not bringing up any sputum. There was no family history of syphilis. [illegible] died in in [illegible]

Dr. G. C [illegible] of the C [illegible] Diarrhœa and vomiting began in the first week and ceased on March 28th. The bowels were then not opened until admitted to hospital on April 2nd. The abdomen was then [illegible] after treatment with enemas and aperients, normal motions were passed and the distension had disappeared. It then [illegible] bismuth, was obviously dilated, forming a U-shaped tube with the base of the U at the splenic flexure, the ascending and transverse colon forming one leg of the U and the [illegible] ted the surgeons to pass [illegible] ation was advisable.—Dr. [illegible] gnosis was to rest on the [illegible] cure basis, especially when [illegible] of starch and bismuth had been injected into the colon under a constant pressure, and that unless the plate was pressed down on the colon there would be a considerable spreading of shadow. The darkness on the right side of the U was also contributed to by the did not understand why the case was spoken of as congenital, because even if [illegible] Dr. Carpenter the child [illegible] its attack of abdominal [illegible] bismuth and starch were injected into a child's colon it would easily become dilated.—Mr. J. P. LOCKHART MUMMERY said the diagnosis could be cleared up by the use of the [illegible] that he still thought [illegible] nosis on rectal and [illegible] x ray picture. There was no doubt about the thickening and what else could it be due to? He would be glad to afford an opportunity for examination by the sigmoidoscope.

Dr. CARPENTER showed a specimen from a case of Steeple Skull exhibited to the section in December last. The child was at that time five weeks old and died some little time after its exhibition. The specimen was the skull bisected in the median line.—Mr. [illegible] the condition, and Dr. [illegible] should be referred to [illegible] PENTER replied that he would not enter into a discussion of the skull before a full description had been written.

Mr. A. R. THOMPSON showed a case of Solution of Continuity of the Right Clavicle since birth. The mother had fallen down some two weeks before the birth of the child. No deformity was noticed at birth. The boy showed a right clavicle which had apparently been fractured, the two portions being connected by a false joint and forming an inverted V. Mr. Thompson thought *the case was one of fracture, although such cases* suggested the possibility of cleido-cranial dysostosis.—Mr. A. H. TUBBY said this condition first came under his notice two or three months ago in a child aged ten months. The labour had been a difficult one, the arms being behind the shoulders. On bringing the arms down a distinct crack was heard, and there was found to be a deformity of the clavicle similar to that in Mr. Thompson's case. He operated and found an ununited fracture with a false joint and wired the fragments together. He had seen a similar case in which, despite wiring, no true union took place, and feared that in Mr. Thompson's case there would be no true union even if the false joint were excised.—Dr. SPRIGGS agreed that there was a fracture of the clavicle and not cleido-cranial dysostosis. In most ca [illegible] the clavicle of which he had [illegible] evidence of deficiency of the [illegible] for instance, published by the late Mr. Walsham and in the photographs of Dr. Carpenter's cases there was evidence either of an unclosed fontanelle, a globular cranium, a high-arched palate, irregular teeth, or some deformity of the lower part of the sternum. The present case showed none of these. Again, in cleido-cranial dysostosis, although there was usually some irregular deformity of the clavicle on both sides, the fragments might be joined together by a loose joint, in which case the two parts fixed themselves in the same position as in this case. The case was an interesting one historically, because a number of cases of cleido-cranial dysostosis had been recorded as fractures even when the deformity was bilateral Some anatomists, such as Paterson of Liverpool, thought that the clavicle might be developed in two parts.—Mr. LUCAS expressed his agreement with those who had spoken. He thought that operation should be undertaken.

Dr. SPRIGGS showed a case of Multiple Exostoses. The boy went to St. George's Hospital in 1902, aged five years, with a painful tumour in the upper end of the left tibia. At that time he showed several other small exostoses. Five years later, at the age of ten years, he went to the Victoria Hospital and then showed exostoses of the vertebral borders of the scapulæ, on the spine of the right scapula, at the insertion of the pectoralis major in the right humerus, at the lower end of both radii and ulnæ, on a left metatarsal, on the femora and tibiæ, and at the inner and outer ends of each clavicle. At that time he had a good deal of pain and could not dress without assistance. Muscular power was fair. At present (two years later) the bony tumours were definitely less marked. The case was interesting as showing a few tumours at the age of five, more at the age of ten, and a diminution in their relative size since.

Dr. W. A. Milligan read a paper on a case of Meningitis associated with the Leptothrix Bacillus. A child, aged four and a half months, was admitted to hospital with a history of a fall on the head three days previously. There were general rigidity, conjugate deviation of the eyes to right or left, with lateral nystagmus. Craniotabes was present as well as a bulging anterior fontanelle. The temperature was 101° F. and the pulse was 104. A milky fluid was withdrawn by lumbar puncture which contained an excess of polymorphonuclear leucocytes and a leptothrix bacillus, of which a photograph was shown. The organism was Gram-negative and no growth was obtained either on agar-agar or blood serum. The illness ran an acute course, the child having a varying temperature and dying on the fifth day after admission. A subdural meningitis was found post mortem, extending over both hemispheres, especially over the vertex in front. There was an extravasation of blood on the side of the skull on which the child had fallen. The meninges were congested. Examination of the pus revealed the presence of the diplococcus pneumoniæ. On opening the right ear, a small bead of pus welled up. A case of pyæmia and meningitis associated with a pathogenic leptothrix bacillus had been described by Ritchie and McDonald, who also spoke of terminal pneumococcal infection. McDonald had recorded five cases in which he found organisms similar to those described above in an epidemic of cerebro-spinal meningitis and had concluded that the leptothrix was not a contamination. Dr. Milligan thought that the presence of leptothrix was more easily explained as a secondary infection, as this bacillus does occur about the mouth and throat.—Dr. Cautley said that the important point was whether the leptothrix was a cause of meningitis or a secondary infection. He had seen many cases of meningitis of that type but without the leptothrix bacillus. The clinical course seemed to point to a pneumococcal infection.

Mr. N. Bishop Harman read a paper on the Effects of School Life upon the Vision of the Child. After reviewing previous statistics, he communicated the results of the examination of 1100 children, seen at the Belgrave Hospital and the Middlesex Hospital. In all cases the eyes were under the influence of atropine, the ointment of 1 per cent. having been used four times a day for a week. Of every 100 children with defective vision, over 71 had hypermetropia and less than 29 were myopic. These 100 children represented about 10 per cent. of the school children, and so the incidence of myopia amongst school children in London might be considered not to exceed 3 per cent. About 78 per cent. of the cases were girls. This Mr. Harman attributed to the girls having less outdoor exercise and not being in such a healthy condition, as well as to the fine needlework done in school by the girls. During the school age the incidence of hypermetropia increased, as might be expected from what was known of the growth of the crystalline lens. At the same time the curve of myopia rose upwards to the highest positions on the chart, and such a phenomenon as this led to the conclusion that the diminution of the hypermetropic astigmatism had been due to the transference of these cases to the myopic group. On the whole the condition of the eyes of London children was very fair, especially if they compared them with similar returns collected in Germany. The greater proportion of the cases of bad vision were due to natural conditions of the eye—that is, hypermetropia and hypermetropic astigmatism. New-born infants were always hypermetropic. The incidence of "manufactured" bad vision—myopia and its associated astigmatisms—formed between a quarter and a third of the whole of the cases. The evidence of the deterioration of astigmatic eyes indicated the desirability of a special oversight of these cases. Mr. Harman did not think that a healthy school life was harmful to the sight of the child population. In conclusion, Mr. Harman criticised adversely the paper on the Inheritance of Vision by Miss Amy Barrington and Professor Karl Pearson. Several points in his experience led him to different conclusions. Miss Barrington and Professor Pearson would lead us to suppose that the increase of myopia was due to fate and hopeless, but in practice it was found that the amelioration of school conditions and the relief of strain in ill-shaped eyes did stay the increase.—Mr. Sydney Stephenson congratulated Mr. Harman upon the clearness of his exposition. He agreed that it was futile to examine children's refractions unless the accommodation had been paralysed by atropine. Some years ago he examined 6000 eyes, under the Poor-law, in children ranging from 18 months to 18 years of age. In these he found myopia present in 6·68 per cent. That was not very different from Mr. Harman's figures when the different range of ages was considered. He agreed that among the poor children of this country myopia was not of serious frequency. In his own figures the females were almost twice as much subject to myopia as were the males. He agreed in ascribing this to their employment in indoor work and lack of healthy exercise.—Mr. E. Clarke agreed with Mr. Harman and Mr. Stephenson on the great importance of insisting on the use of a cycloplegic. The statistics concerning the refraction of young people which were published without such were useless.

LIVERPOOL MEDICAL INSTITUTION.

Treatment of Tetanus.—Intra-spinal Tumour.—Meningococcic Meningitis in Children.

The last meeting of the session of this society was held on April 29th, Mr. T. H. Bickerton, the President, being in the chair.

Dr. J. Lloyd Roberts reported a case of Tetanus which had recovered under treatment with injections of carbolic acid and of antitetanic serum. The disease followed an injury to the hand from a circular saw. Symptoms appeared ten days after the accident, and treatment was commenced on the sixth day of the disease. On the fourth and fifth days the symptoms had rapidly become more severe, and on the sixth day there was marked trismus, &c. The patient received 10 cubic centimetres of serum every 12 hours, and 15 minims of a 4 per cent. solution of carbolic acid every three hours for one day, and subsequently every two hours. On the second day of treatment the disease appeared to be arrested, and the patient was well 20 days later. 26 injections of serum and 236 injections of carbolic acid were given. The favourable result was attributed to the carbolic acid rather than to the serum.

Dr. John Owen and Mr. D. Douglas-Crawford communicated a note on a case of Intra-spinal Tumour which they had had under their care. It was localised at the eighth dorsal segment and was successfully removed, the patient being shown at the meeting. They hoped to publish a full account of the case later.—Dr. W. B. Warrington discussed the rarity of these cases and urged the importance of physicians having sufficient faith in their diagnosis to urge an operation.

Dr. N. P. Marsh and Dr. O. T. Williams communicated a paper on Meningococcic Meningitis in Children. They referred to the importance of lumbar puncture in the diagnosis of tuberculous meningitis from other types of the disease. In the last 14 cases of tuberculous meningitis they had recovered the tubercle bacillus from the cerebro-spinal fluid. Four cases of tuberculous meningitis with secondary meningococcic infection were described in detail. The use of Flexner's serum had reduced the mortality from between 70 and 80 per cent. to 29·6 per cent. In children under two years of age the mortality was 42·4 per cent. in 59 cases, and in these the higher mortality was amongst those not treated until the seventh day of the disease. The serum was described and its effect both on the organisms and the cytology of the fluid; being bactericidal and only slightly antitoxic the serum must be injected into the spinal canal. 14 cases of cerebro-spinal meningitis were considered. They varied in age from three months to four years, and seven recovered. Three cases treated in the first few days of illness all recovered. The amount of serum used in each case varied from 10 cubic centimetres up to 130 cubic centimetres, and the number of injections from one to five. In infants they advised small doses of from 10 to 15 cubic centimetres. Dr. Flexner confirmed this view. In older children they followed Dunn of Boston and gave 30 cubic centimetres on four successive days, the results upon symptoms and the fluid guiding their future procedure. They considered that this serum in early cases promised extremely good results and even in later cases it favoured the prognosis.—Dr. Owen referred to one case he had treated with the serum with satisfactory results.—Dr. A. G. GULLAN referred to two cases: in one the fluid was not typical nor was the diplococcus found. The patient recovered under treatment with Flexner's serum. The second case, a girl aged 18 years, had been ill a fortnight; after the first injection the patient passed into a state of coma and in spite of further lumbar punctures and injections died.—Dr. JOHN HAY referred to the occasional difficulty of differentiating in certain cases between acidosis and meningitis, and related a case illustrating the point.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.

A MEETING of this society was held on April 23rd, Dr. W. H. CHEETHAM being in the chair.

Mr. H. LITTLEWOOD showed the following cases: 1. A case of Malignant Pustule, with Recovery after Injection of Sclavo's Serum (without excision). The patient, a man, aged 41 years, noticed on April 2nd a "small pimple" on the right eyebrow. Two days later the forehead and eyelids were swollen. On admission on April 5th a central black slough of the size of a sixpenny-piece was present with two or three vesicles around it. There was considerable œdema. No general symptoms were evident. Anthrax bacilli were demonstrated. 40 cubic centimetres of Sclavo's serum were injected at once and 30 cubic centimetres on the following day. The temperature was normal after four days. All the œdema disappeared in a week, and a good recovery was made. 2. A Calculus removed from "Horseshoe" Kidney. Two other shadows on the skiagram proved to be calcified tuberculous glands in the mesentery. The skiagram showed a small shadow at the upper pole of the right kidney and one larger one in the region of the lower poles of both kidneys. On Feb. 22nd nephrotomy was performed on the right side. The kidney was found to be of the "horseshoe" variety. A stone in the upper part of the right kidney was found. Other shadows were not accounted for. On April 1st, after a further skiagram had been taken, the abdomen was opened in the mid-line. Two masses of calcified glands found in the mesentery were removed and recovery was uneventful.

Dr. T. CHURTON showed the following cases: 1. A case of Acute Myelitis of the Conus Medullaris, probably Syphilitic. The patient, a man, aged 28 years, experienced on March 10th a sudden weakness in the left leg but it lasted only a few hours. 14th: The patient passed urine freely at 10 A.M. but at 5 P.M. he was unable to do so. 15th: At 11 A.M. some urine dribbled away. Catheterism became necessary then and afterwards. 24th: On awaking, sensation was found to be lost below the left knee and motion to be lost from the hip to the toes. Sensation returned, as well as partial control of the bladder. One year ago a rash appeared on the trunk, the arms, and the legs; it lasted six weeks and was untreated. 2. A Temperature Chart from a case of Cerebral Hæmorrhage (Ventricular) which proved fatal in 16 hours, showing the differential rise on the paralysed side within three hours of the onset and becoming equal (101° F.) soon after somatic death.

Mr. J. F. DOBSON showed the following: 1. Three cases of Perforated Duodenal Ulcer, in which the Perforation was Sutured and Gastro-enterostomy was Performed. The first case was that of a male, aged 31 years, who was admitted to the Leeds Infirmary 24 hours after perforation. There was a large quantity of fluid in the abdomen. In the second case, that of a male, aged 29 years, perforation had occurred on the day before admission. In the third case, that of a male patient, perforation had occurred almost immediately after a mid-day meal and an operation was performed within eight hours. In all these cases drainage was effected through a tube into Douglas's pouch and another into the right kidney pouch. In the second case there was little extravasation around the perforation, but a large quantity of fluid in the pelvis. 2. A case of Rupture of the Liver. The patient was admitted to the Leeds Infirmary shortly after having been run over. He was not markedly collapsed, though there were some signs of fluid in the abdomen. On the following morning he was much worse and was clearly suffering from internal hæmorrhage; the abdomen was rigid, with shifting dulness. On opening the abdomen a large amount of blood escaped, and a rent was found at the back of the right lobe of the liver, which would admit the hand; on removing some clots free bleeding occurred. The hæmorrhage was stopped by firmly packing the rent with gauze. The packing was retained for a week and caused some suppuration.

Mr. A. L. WHITEHEAD showed (1) case in which vitreous degeneration had followed hæmorrhage into the anterior and posterior chambers, caused by a blow from a stone; and (2) a case in which a piece of steel was removed from the vitreous six months after entering the eyeball.

Mr. R. LAWFORD KNAGGS showed a case of Duodenal Fistula in which gastro-enterostomy and infolding of the pylorus were performed successfully. The patient was a female, aged 19 years, who had had abdominal symptoms from August, 1906, to January, 1907, when a local suppurative peritonitis was drained. In two months there were signs of duodenal fistula. In July posterior gastro-enterostomy was performed. The pylorus was pleated into a solid roll. In six weeks the fistula closed. In April, 1909, the sinus had quite healed.

Dr. CHURTON and Mr. LAWFORD KNAGGS showed a case in which there had been Symptoms of Gastric Ulcer and Œsophageal Obstruction. The patient, a female, aged 40 years, had had indigestion for 20 years. For the last 12 months pain had been coming on directly after food, and this was relieved by vomiting. The point of maximum tenderness was one and a half inches above the umbilicus. There was pain in the throat on swallowing as well as great wasting. On March 22nd the stomach and duodenum were explored but there was no sign of ulcer. Previously the stomach had been washed out (evidently it was the dilated œsophagus above the stricture—in which the stomach tube must have coiled up—that was washed out). After a temporary improvement vomiting returned (with large quantities of watery fluid). Being regarded as neurotic, an attempt was
made to feed the
that this did not
up bent at an ang
Since this operat
was rapidly impr
showed the dilat
narrow stricture o
one of spasm, possibly associated with ulcer close to the cardiac orifice of the stomach.

Dr. A. G. BARRS with Mr. B. G. A. MOYNIHAN showed a case of Perforated Typhoid Ulcer occurring at the end of the second week. Treatment consisted of suture and drainage.

Dr. W. H. MAXWELL TELLING showed the following: 1. A case of Disseminated Sclerosis with Optic Neuritis. There had been typical symptoms of seven months' duration. One month after the onset the sight of the right eye failed rather suddenly. On examination five months later there were moderate optic neuritis with atrophic changes in the disc in this eye and very slight and doubtful neuritic changes in the left eye. The visual fields were diminished in both eyes. In the right there was a central scotoma to white and green, and by this eye red was not visible as red. 2. A woman of normal mentality, aged 24 years, with Adenoma Sebaceum, which had been present for 21 years. 3. Two cases of Molluscum Contagiosum. In one case the nodules were scattered over the body; the eruption had been present for 30 years. In the second case the first nodule appeared on the penis a fortnight after infection and was followed by a small crop adjacently.

MEDICO-LEGAL SOCIETY.—A meeting of this society was held on April 27th, Dr. F. J. Smith, Vice-President, being in the chair.—Mr. A. Douglas Cowburn read a paper on Some Aspects of the Legal Responsibility of Medical Men. The motive actuating every man assisting another in illness must be, he said, to heal, to relieve suffering, and to prolong life. If he intentionally used any means to shorten life he was guilty of
any person, whether qualified
not, who professed by way of
life or health of His Majesty's subjects, was bound to possess competent skill to perform the task that he held himself out to perform, and was also under a duty to treat those under

in cases where the operation is performed before the rupture of the membranes, is quite unnecessary, as the liquor amnii has been shown to be aseptic, and the delivery of the uterus necessitates a much longer abdominal incision than is otherwise required. The use of an elastic ligature to prevent hæmorrhage is another procedure which has been given up by almost all operators of any experience, and one hardly expects to find at the present day the advice to use a drainage-tube after total abdominal hysterectomy.

Dr. Richard Norris writes on the important question of operations undertaken during pregnancy, and Dr. Barton Cooke Hirst on the operative treatment of sepsis in the child-bearing period, a title which hardly expresses accurately the scope of the section, referring as it does to puerperal sepsis. Dr. Hirst, on the whole, seems to favour interference in some of these cases; thus he quotes an instance in which the patient recovered after removal of the uterus although she had general systemic infection and septic pneumonia, a case which to us appears only to prove that many of these patients recover in spite of the treatment. This fact Treub, whose statistics the author quotes, has demonstrated in recording 724 cases of puerperal infection with 34 deaths, or a mortality of about 4·6 per cent., while, on the other hand, in 61 cases reported by Fehling in which hysterectomy was performed there was a mortality of 55·7 per cent.

Dr. Whitridge Williams contributes a very good account of extra-uterine gestation. The fact that decidual formation probably follows and does not precede the imbedding of the ovum is surely a strong argument against, and, indeed, would seem to negative altogether, the theory that decidual formation in the tube can be a possible cause of a tubal pregnancy. The author gives a very good *résumé* of the literature. The next chapter by Dr. J. C. Bloodgood contains a detailed and trustworthy account of diseases of the female breast, with a large number of exceedingly good illustrations, many of them coloured. A full description of the operative technique adopted in Halsted's clinique is given with a number of drawings. The very good results which are obtained after these extensive operations, as regards the functional use of the arm, are well shown in Figs. 541 and 542. There does not appear to be any reference in the chapter to Sampson Handley's important work on the lymphatics of the breast and its bearing on the various methods of operating. Operations on the gall-bladder, bile-ducts, and liver are described by Dr. Albert Ochsner in an admirable manner, full credit being given to the work of Mayo Robson and others in this branch of surgery.

The fact that the section dealing with operations on the stomach is contributed by Mr. B. G. A. Moynihan will show that it contains all that there is to be said on these important surgical procedures, and it is illustrated by a number of excellent illustrations by Mr. H. Becker. The article on pyloroplasty is from the pen of Dr. J. M. T. Finney. The chapter on intestinal surgery extends over more than 100 pages and is by Dr. J. B. Murphy. When we mention that the description of diseases of the appendix is written by Dr. Howard Kelly and Dr. Elizabeth Gurdon the reader will know that it is full of information. The chapter on the surgery of the spleen and that on the ureter are also written by Dr. Kelly, and are both good. Dr. Kelly recognises the extreme difficulty which often attends the treatment of ureteral fistulæ and is not very optimistic about the results of such operations. In his article on tuberculosis of the peritoneum Dr. G. B. Johnston voices the opinion of many surgeons of the present day when he concludes that in an affection of this kind "one's first efforts should be directed towards treating the patient, while the second consideration has to do with the best method of handling the local process." It appears very likely that the surgical treatment of such cases will give way more and more in the future to treatment by the physician.

One of the most interesting sections in the whole work is that giving an abstract of the literature of penetrating wounds of the abdomen in the chapter on that subject. The perplexing problems involved in the treatment of various septic conditions, with or without drainage, are discussed in detail in a chapter on the use of drainage in pelvic and abdominal surgery, by Dr. Brooke M. Anspach. The great advantages in many instances of drainage in the female by an incision through Douglas's pouch—a method which is too much neglected by the general surgeon—are rightly laid stress upon, and the ease with which it can be carried out is shown.

The surgery of the kidney is fully considered in a chapter extending to nearly 100 pages by Dr. C. P. Noble, in conjunction with Dr. Brooke Anspach. A very striking illustration in a book containing many fine drawings is that of a case of polycystic disease of the kidney.

The whole work reflects great credit on all concerned in its production and should prove of great value to all surgeons and practitioners. As we have already mentioned, the illustrations leave nothing to be desired and the printing and index are both excellent.

Neurasthenia. By GILBERT BALLET. Translated from the French by P. CAMPBELL SMITH, M.D. Durh. London: Henry Kimpton. 1908. Pp. 408. Price 6s. net.

THE present English edition has been taken from the third French edition, which appeared last year. The matter of the original work is wholly admirable, and the English form in which it has been clothed by Dr. Campbell Smith has in no way taken from its value. Indeed, the translator has succeeded in no small degree in reproducing in our tongue the terse directness of the original.

We note with satisfaction the stress which Professor Ballet lays upon defective education as an etiological factor in the production of neurasthenia. Our educational system, in endeavouring to produce strict uniformity in its methods, finds many for whom these methods are unsuited, with the result that the child, instead of starting life endowed with a firm will and enlightened judgment, has become capricious and obstinate, being devoid of strength of will and moral firmness. Over brain pressure in schoolboys shows itself in two forms: one in which there are insomnia, irritability, a nervous laugh, and palpitations; the other in which there are yawning, a frequent desire to sleep, inattention, and an expression of languor. Whereas the element of heredity is an important one in certain forms of neurasthenia, it is desirable that the education of children with a hereditary neurotic predisposition should pursue a triple aim: firstly, to develop harmoniously all the capacities of the individual; secondly, to keep down any tendency that may disorder the physical and moral equilibrium; and thirdly, to strengthen the energy and the physiological power of resistance of the nervous system. All moral education must aim at the following end: to convince the child that he is capable of good, and to make him believe that he has a will and may be master of himself. Nothing is so enervating, nothing so fitted to unbalance and weaken the nervous system, as to be wholly taken up with the pursuit of pleasure and the satisfaction of the least elevated and least noble desires. A lively interest in the useful part that each of us can fill in his position, according to his aptitudes and faculties, is not only a moralising element, but is also in certain respects a condition of health. Neurasthenia is often the natural but regrettable penalty paid by uselessness, idleness, and vanity.

The author is judicious in his remarks on the subject of psychotherapy. This is no new method of treatment, as we have ourselves pointed out, but it has lately been extolled to such an extent in certain quarters that it has been elevated into a panacea. It is, in fact, a system no more applicable to all cases than is electricity or hydrotherapy, and we only do harm if it is tried to employ it in all cases of the psychoneuroses without distinction. The good doctor is not he who has a system of his own, and applies it to all cases empirically, but he who is able to distinguish special indications and to adapt his treatment to the individual psychology of each patient. With these reservations psychotherapy is, in the author's opinion, of the greatest service in neurasthenia. So, too, of hypnotism. This method, useful to combat this or that incidental symptom of psychical nature arising in the course of nervous exhaustion, cannot be reasonably proposed as a mode of general treatment of neurasthenic conditions. Indeed, there is some danger in accustoming the patients to induced somnambulism, and not a few cases could be quoted in which hypnotism has manifestly determined the appearance of mental disorders of real gravity.

We are glad to note that the author is of opinion that the term "psychasthenia" should not be attached to the strongly marked borderland cases to which there is now a tendency to apply it. The term at present serves to denote the mental fatigue and the inability for brain work of simple neurasthenia, and it is a pity to change the meaning of the word to make it include other and very different states. The author gives us a long and exhaustive chapter on diet. The difficulty of this part of the treatment is notorious, and the practitioner will find here many useful hints to assist him in his arduous task.

We can confidently recommend this practical work. It has justly taken a high place in the literature of neurasthenia.

American Practice of Surgery. Editors: JOSEPH D. BRYANT, M.D., LL.D., and ALBERT H. BUCK, M.D. Complete in eight volumes. Profusely illustrated. Volume V. New York: William Wood and Company. 1908. Pp. 965. Price per volume, $7.

THE very important section of the Surgery of the Head has been undertaken by Dr. Edward Archibald of Montreal, and the article extends to 378 pages; in fact, it forms in itself an excellent treatise on cranial and cerebral surgery. Dr. Archibald discusses very fully the pathology of compression of the brain and his description is clear. The difficult subject of concussion of the brain receives a very full examination, and the author comes to the conclusion that concussion is at first due to a combination of mechanical and vascular disturbance, the vascular disturbance being a temporary anæmia. The more prolonged unconsciousness of concussion he considers to be due to the persistence of a partial anæmia, itself the result of an almost immediate interference with the capillary circulation by minute thromboses, and succeeded by the rapid development of intracerebral, or more especially of intra-cortical, œdema sufficient to induce an increase of cerebral pressure, while associated with this is a loss of the vaso-motor tone. The surgery of intracranial tumours is well described. Altogether the article is exceedingly good.

Dr. Charles H. Frazier of Philadelphia has written on the Surgery of the Cranial Nerves, and naturally most interest is connected with the fifth nerve. The various operations for severe tic are given, and Dr. Frazier then describes an operation he has devised for the division of the sensory fibres passing to the Gasserian ganglion. The method has been employed almost exclusively at the hospital of the University of Pennsylvania since 1901 with very satisfactory results. The ganglion is approached by the "auriculo-temporal route," and the patient is placed in the sitting position in order to lessen the hæmorrhage. The method is fully described and it deserves more attention than it has hitherto received.

Dr. C. G. B. de Nancrède of Ann Arbor has contributed the article on Surgical Diseases and Wounds of the Face. It is well illustrated and contains a very readable account of the surgery of this portion of the body. We may point out that the clinical and histological differences between ordinary squamous-celled carcinoma of the face and rodent ulcer are sufficiently clear to justify a greater distinction being drawn between them than is made here.

Dr. J. S. Stone of Boston, Massachusetts, has written the chapter on Harelip and Cleft Palate. On the question of the age at which a cleft palate should be treated Dr. Stone gives the ordinary arguments, and he arrives at the conclusion that the surgeon should wait at least six months and that waiting for 10 to 15 months would do no harm; he thinks, however, that the Brophy operation may be of value. In this country Mr. Arbuthnot Lane is the chief exponent of the early operation, and his operation is described in this chapter. Sufficient stress, however, is not laid on the value of the early operation in preventing the nasal voice; the condition is due to an arrest of development, and like other instances of this the earlier the tissues are put into a normal position the more closely will they approximate to the normal. Increased care is undoubtedly needed in the nursing of these cases, and the operation is distinctly more difficult the younger the patient, but the advantages are great.

The section on the Surgery of the Eye, by Dr. George C. Harlan of Philadelphia, is much fuller than is usually to be found in a treatise on general surgery. It occupies more than a hundred pages, and in addition to many illustrations in the text it has some good coloured figures. The account is very good and clear. We must, however, demur to the statements that molluscum contagiosum is derived from a sebaceous gland and that it is not contagious.

Dr. Robert Lewis, jun., of New York City is responsible for the article on the Surgery of the Ear. The description of the operation on the mastoid process and its communicating cavities is particularly deserving of mention. The closely allied subject of sinus thrombosis of otitic origin is dealt with by Dr. John D. Richards of New York City. The author is in favour of resecting the jugular vein rather than merely tying it, and he prefers that the resection should be performed low down, so as to prevent as far as possible the establishment of a collateral circulation. The account of the surgery of labyrinthine suppuration is especially good, and it has some excellent original illustrations. The section on the pyogenic diseases of the brain resulting from ear disease is from the pen of Dr. H. Ottridge Reik of Baltimore. In exploring the brain substance for an abscess he prefers a narrow knife and a "cigarette drain" for drainage of the abscess cavity.

Dr. Charles H. Knight of New York City has contributed a valuable article on the Surgery of the Pharynx, but we think that to employ the adjective "barbaric" to the operation of enucleation of the tonsil is unnecessarily severe. Dr. J. E. Newcombe is the author of the section on the Surgery of the Larynx and Trachea. This includes a good description of the methods of direct laryngoscopy and bronchoscopy. Laryngectomy is described by Dr. Frank Hartley, and with such a distinguished author it is hardly necessary to say that the account given is all that it should be.

Altogether this volume is fully up to the standard of its predecessors. We would suggest that it would assist busy readers if the contents of each volume could be indicated on the wide extent of the data on which his calculations are based, Dr. Forsyth contends that in the nature of the case these returns cannot generally be pathologically exact. He therefore raises the question, "Whether the official figures truly reflect the fatal conditions of infancy at the present day, and how far they carry us in devising remedial measures." In the course of an able criticism of the national death records, Dr. Forsyth comments on the prominent positions occupied by "marasmus" and convulsions, and on the relatively subordinate importance apparently attaching to syphilis, tubercle, and rickets. Whilst fully recognising the difficulty met with by even experienced clinicians in interpreting the symptomatology of infancy, he expresses astonishment that so large a proportion as 16 per cent. of the total mortality should be referred to marasmus, and 12 per cent. to convulsions, whilst only 5 per cent. are attributed to tubercle, 1·3 per cent. to congenital syphilis, and 0·6 per cent. to rickets. It is not easy to harmonise clinical experience with these figures. Marasmus, with its official synonyms atrophy and debility, is a term of vague significance, and is generally employed in connexion with diseases of which wasting is merely a symptom. Congenital syphilis is frequently met with in out-patient departments, and is particularly fatal to young children. Yet in the whole of England it is stated to be responsible for little more than 1 per cent. of the total infantile mortality. If hospital experience is to be trusted, this figure considerably understates the fact. The large proportion of deaths, some 20 per cent. of the whole, attributed to premature birth almost certainly includes a considerable number that should have been referred to this disease, and the scarcely less proportion referred to marasmus probably contains others. The general tenour of this criticism applies even more forcibly to convulsions, a term the use of which in medical certification has been forbidden by the Royal College of Physicians of London. The official figures under this heading are believed by many to be worthless for advancing our acquaintance with the fatal conditions of infancy, and we hold them to be actually misleading. They hide, under a meaningless designation, important fatal conditions, the returns for which are unduly minimised. In conclusion, Dr. Forsyth expresses the hope, in which we heartily concur, that the publication of the Evelina Hospital statistics will lead to the preparation of corresponding figures for other hospitals. By this means a far-reaching and practical measure will have been secured for diminishing the present excessive waste of infant life.

Rheumatic Fever.

In the Lumleian Lectures delivered this year before the Royal College of Physicians of London (the concluding lecture being published at p. 1297 of this issue) Dr. Norman Moore selected a subject which is of widespread interest—namely, Rheumatic Fever and Valvular Disease. In the older textbooks rheumatic fever, or as it was, and indeed is, frequently called "acute rheumatism," was classified under "Diseases of the Joints," but in the "Nomenclature of Diseases," drawn up by a joint committee appointed by the Royal College of Physicians of London, it is now rightly placed under "Infective Diseases." As Dr. Moore pointed out, it is so common a disease that every physician has seen very many examples of it, yet its natural history is still obscure in several directions. He also remarked that its name recalls a pathology long anterior to the revival of learning. His erudite and interesting account of the historical literature of the disease will be found most attractive. Following the usual course of knowledge about any particular disease, some prominent symptom was first noticed and then assumed to be the whole disease—in the case of "acute rheumatism" the affection of the joints was naturally selected as the predominant feature—but progressive observation has gradually demonstrated that this prominent symptom may be a result of several distinct morbid conditions. Thus, the single disease of past generations of medical authorities comes to be divided into two or more separate maladies, and separate terms are necessary to distinguish them. The distinction between typhoid and typhus fevers is an example of this advance of knowledge. In the case of "rheumatism," although the nosology of affections of the joints leaves much to be desired, yet it is now recognised that rheumatic fever is a distinct disease, entirely apart from other acute, subacute, or chronic affections of the joints, such as septic arthritis, gonorrhœal rheumatism, chronic rheumatism, and the various conditions classified under the term "rheumatoid arthritis." We endorse Dr. Moore's contention that since it is desirable to avoid the suggestion of any pathological relation to chronic rheumatism, it would be better for the term "acute rheumatism" to fall out of use, and that the words "rheumatic fever" be invariably adopted. We also join in the protest against the term "subacute rheumatism," which he considers should never be used, as it naturally suggests an absence of importance which attaches to no case, however slight, of rheumatic fever.

We have said that it is now generally accepted that the condition we are considering must be placed amongst the specific fevers, but at present it must be reckoned amongst those fevers the bacteriology of which remains uncertain. Numerous investigations have been made on the subject, and several observers have claimed to have isolated the pathogenic organism. Dr. F. J. Poynton and Dr. A. Paine described a diplococcus which they concluded was *a* cause of rheumatic fever and from further experiments believed it to be *the* cause, and Dr. J. M. Beattie isolated a similar organism. By intravenous inoculation the last-named observer produced endocarditis, polyarthritis, and chorea—a combination of lesions similar to those occurring in connexion with rheumatic fever. Other investigators, however, have failed to corroborate these observations, and the "micrococcus rheumaticus" cannot yet be accepted as the true bacteriological factor of the disease. Dr. W. Bulloch maintains that it does not fulfil all, or indeed any, of Koch's postulates. It is not found, he says, in every case of the disease, and the effects which it produces experimentally do not differ essentially from those produced by cocci having nothing to do with rheumatic fever. But although the bacteriology must still be left in doubt, there is no uncertainty about the pathology of the malady, the essential phenomena being found in the joints and in the endocardium. Hitherto the condition of the joints has been considered as the principal element in rheumatic fever; Dr. NORMAN MOORE, however, insists that the endocarditis is not to be regarded simply as a frequent complication, but as the essential and invariable feature of the affection. He maintains that endocarditis is always present, and that in most cases, but not in all, it produces some permanent alteration in one or more valves. In proof of this assertion he states that, if the heart in a mild case of rheumatic fever is only auscultated at the beginning and end of the disease the sounds may sometimes seem to be unaltered, and it may therefore be assumed that they have been normal throughout, but if the heart is examined daily changes in its sounds will, in his experience, always be discovered. He considers that this fact, taken in conjunction with the evidence of the frequency of definite valvular diseases as a result of rheumatic fever, and with the frequency of a history of rheumatic *fever in cases of valvular disease belonging to the first half of* life, justifies the belief that those variations in sound may be taken as evidence of the presence of endocarditis, even though no permanent valvular lesion may ultimately be produced. He further mentions in support of his argument a *fact that is generally accepted—namely, that the size or* number of the joints affected has no direct relation to either the severity of the endocarditis or to the seriousness of the consequent valvular disease. Referring to the etiology of the disease, Dr. MOORE expresses the opinion that, whatever the point of entrance and line thence of travel, the endocardium is to be regarded as the invariable centre and primary region of growth of the pathogenic organism, so that the swollen joints may be considered as "so many colonial settlements proceeding thence."

Dr. MOORE'S remarks call for careful consideration. In support of the statement that the affection of the joints is not the primary seat of the disease, a consideration of the changes which occur in them is of interest. The lecturer pointed out that the affected joints appear to recover completely; he has not seen a single case of stiff joint from this cause in his wards during the last six years. If a patient dies during the attack as the result of cardiac failure no characteristic changes are found in the structures of the joints, neither thickening nor results of degeneration. There may be an increase in the quantity of synovial fluid, but the hyperæmia which probably existed during life has disappeared. There may be also temporarily a swollen and infiltrated condition of the synovial membrane, but if the patient had lived this would have subsided, leaving the tissues perfectly healthy. Another suggestive fact is demonstrated by a clinical feature which is sometimes noticed in individuals who have recovered from an attack of rheumatic fever, but are suffering from the effects of the endocarditis, in most cases a lesion of the mitral valve. If the temperature is taken regularly occasional moderate rises of temperature will be noticed; may not this be caused by the presence of the organism still in a state of activity in the endocardium? Dr. MOORE records several cases which would support this view, and asks the question, Does the organism cease to exist when the disease is apparently at an end, as does the pneumococcus of pneumonia, or does it, like the tubercle bacillus, live on indefinitely in the body, maintaining its lodgment for a time, not spreading, then again multiplying and doing more injury, sometimes finally dying out? We are inclined to the latter view, and in addition to the clinical phenomenon we have just mentioned the course which rheumatic fever often follows in children is significant. In young life endocarditis comes on in an insidious progressive form, and the arthritis may be slight or at the time inappreciable. In subsequent years a valvular lesion is discovered, indicating for the first time the true nature of the former illness. In further support of the continued presence of the pathogenic organism in the endocardium, Dr. MOORE adduces the fact that many attacks of the disease occur in the same individual, suggesting that these attacks are successive developments of an organism which has never been eradicated. We have only considered one division of the Lumleian Lectures; the remarks on valvular disease and the prognosis and treatment of rheumatic fever are equally interesting, and, as is always the case when Dr. NORMAN MOORE is the author, the attractive literary style and wide general information lend a charm to his statements, deductions, and suggestions.

◆

Is Beri-beri Caused by Rice?

BERI-BERI has been hitherto regarded as a mysterious disease which has defied the efforts of investigators, but there are grounds for believing that its etiology is now in a fair way to be solved. The chief views which have been held as to the causation of this malady have been: (1) that it was a peripheral neuritis of paludal origin; (2) that it was due to nitrogen starvation; (3) that it was a microbial infectious disease; and (4) that it was caused by a toxin the product of a saprophyte outside the human body. All of these theories have been investigated, more especially by those who had opportunities for studying the disease in the Malay Peninsula and East Indian Archipelago, in which region it is estimated that nearly a fifth of the population suffer from the malady. There has been of late an increasing consensus of opinion that beri-beri is due in some way to the consumption of rice, and the arguments in favour of this view have been recently restated by Dr. W. LEONARD BRADDON of Selangor, Federated Malay States, a well-known authority on the subject. In a paper which was read for him by Dr. T. S. KERR at the April meeting of the Society of Tropical Medicine and Hygiene, a summary of which we published in THE LANCET of April 24th, Dr. BRADDON asserts that always and everywhere the uncured rice-eating community (the Chinese) suffered from beri-beri, while the eaters of cured rice (the Tamils) with equal invariability escaped. Also it is beyond dispute that those who eat rice that is fresh (the agricultural Malays and Dyaks) were exempt. So that it is not so much the eating of rice that is the source of the mischief, but the eating of a particular kind of rice—namely, that which is uncured. This uncured rice is the ordinary white rice of commerce imported usually from Siam, Saigon, Burma, or Java, and decorticated in mills by a process which scours away, together with the husk, all the surface layer of the seed. It is nearly always stored for some time before it is consumed and is consequently liable to be "stale." The cured rice used by the Tamils is soaked for a short time, then rapidly steamed, and then dried, after which the husk is easily separated by light milling. The whole of the inner envelope and the surface layer of seed cells, which contain a large part of the total proteins and fat of the seed, are preserved intact. Rice which has lost its protective envelope is obviously likely to deteriorate and become "stale" or mouldy. The presence of a poison developed in stale uncured rice explains, in Dr. BRADDON'S opinion, all the phenomena of beri-beri. The toxic quality of uncured rice is an added effect, either the grain itself becoming altered in its nature or becoming the seat of growth of agents, ferments, bacteria or fungi, which produce a poison of their own. He conjectures that the active agent is some epiphyte existing in or upon the envelope of the rice, and able to invade it saprophytically under appropriate conditions when husked. This epiphyte he maintains to be specific to rice, since the use of no other cereal has been proved to entail beri-beri.

It has been urged against the rice theory of the causation of beri-beri that it is only a coincidence, since the disease is endemic in regions where rice is the staple article of diet. That the occurrence of beri-beri among eaters of uncured rice is no coincidence was proved by the recent observations of Dr. HENRY FRASER and Dr. A. T. STANTON of Kuala Lumpur, published in THE LANCET of Feb. 13th of this year. These observers investigated the conditions under which two parties of coolies, carefully selected and examined, were working in the virgin forest, living in new huts and kept under the most hygienic conditions practicable, one party feeding on cured and the other on uncured rice. In the course of some weeks beri-beri developed among the latter, but was quickly cured when they were put on a diet of cured rice. The party fed on cured rice remained in good health. These observations largely dispose of the theory of infection either of person or place, and show that beri-beri requires no assistance from transmitters such as biting beetles, bed bugs, or body lice, which according to some are responsible agents in diffusing the disease. It was pointed out in 1905 by Dr. C. HOSE, who had spent many years in Borneo, that the rice supplied to the coolies employed on plantations or public works was generally provided by contractors, and was often of an inferior kind, the contractor being tempted to supply the inferior article to increase his own profit. Dr. HOSE had often examined contractors' rice, and he attached suspicion to the constant presence in this mouldy rice of a small beetle or weevil as likely to be related to the cause of beri-beri. Chinese coolies are often conveyed to great distances to labour in plantations or constructive works, and it has been quoted as an argument in favour of the infection theory that the disease was carried by the coolies to their new place of abode. But on the above facts the explanation is easy if it be recognised that the contractors' rice is also carried to the new home, and probably in this case the mischief is intensified by the increased distance and the longer time the rice is in transit. It has often, too, been asserted that the rapid reduction of beri-beri in the Japanese navy was due to the addition of fat pork to the dietary, and therefore that rice could not have been the cause of the disease. It has to be borne in mind that the amount of rice consumed has to be considered. Chinese coolies who consume large quantities of rice suffer most. But if the rice in a dietary be replaced in some amount by animal food the quantity of poison taken must be correspondingly reduced and with it the risk of contracting beri-beri also.

A frequent argument adduced against the rice theory is that beri-beri occurs in ships at sea among European sailors who do not largely live on rice. It has to be remembered that beri-beri is by some regarded more as a clinical than an etiological entity, and that it is very liable to be confounded with other morbid conditions such as alcoholic or arsenical neuritis, malarial cachexia, epidemic dropsy, pernicious anæmia, pellagra, and scurvy. It is therefore possible that ship beri-beri, though clinically resembling the Asiatic variety, is not the same disease. The Norwegian Commission, of which Professor UCHERMANN of Christiania was president, and which was appointed in 1902 to inquire into the origin of beri-beri so common on board Norwegian sailing ships on long voyages, defined beri-beri as "the oriental name given to a multiple neuritis which is due to a toxin intoxication by tainted (stale) vegetable or animal food. The vegetable form closely corresponds to the Asiatic variety, and is usually owing to the eating of tainted rice. The animal form corresponds particularly with the beri-beri which appears on European ships and is due to the eating of tainted tinned food." Whether or not the ship beri-beri be the same as that which afflicts the Chinese coolie does not in our opinion affect the contention, put forward recently by Dr. BRADDON, Dr. FRASER, and Dr. STANTON in our columns, that the eating of uncured rice is the cause of beri-beri in the Far East. There can, we think, be no question as to the incrimination of uncured rice. The point now remaining to be demonstrated is whether the symptoms of the disease are the result of a nitrogen starvation or are due to a toxin produced in the rice by some organism. We look forward with confident expectation that a solution of this problem will be forthcoming from one or other of the scientific investigators who are now working in the regions where beri-beri most abounds.

Annotations.

"Ne quid nimis."

THE POOR-LAW COMMISSION: REPORT ON IRELAND.

THE Royal Commission on Poor-laws and Relief of Distress has issued during the week as a separate volume the report on Poor-law administration with respect to Ireland. Here, also, as in the report dealing with England, we have a Majority and a Minority Report, in addition to which there is a separate Memorandum by the two Irish members of the Commission, the Bishop of Ross and Sir Henry Robinson, criticising the Minority Report, whose report is in itself a criticism of the Majority Report. The Majority Report, which comprises 83 out of 87 pages of the Blue-book, is signed by Lord George Hamilton, the Bishop of Ross, Sir Henry Robinson, Sir Samuel Provis, Mr. F. Holdsworth Bentham, the Rev. Thomas Gage Gardiner, Mr. C. S. Loch, Mr. J. Patten MacDougall, Mr. T. Hancock Nunn, the Rev. L. R. Phelps, Professor Smart, Mrs. Helen Bosanquet, and Miss Octavia Hill, all of whom were signatories of the English Majority Report. The Minority Report, a very brief dissent from the Majority Report, is signed by the Rev. H. Russell Wakefield, Mr. F. Chandler, Mr. George Lansbury, and Mrs. Sidney Webb, *all of whom were signatories of the English Minority* Report; while the separate Memorandum bears, as we have said, the names of the Bishop of Ross and Sir Henry Robinson. The labours of the Commissioners, as far as Ireland is concerned, were much spared by the fact that they felt themselves, at least those who signed the Majority Report did, able to adopt the greater part of the recommendations for the reform of the Irish Poor-law which were published by the Viceregal Commission in Ireland shortly after the appointment of the Royal Commission.[1] An interesting historical summary of Irish Poor-law administration is given in the latest Blue-book, and the various points in which the recommendations of the Viceregal Commission fit with the proposals already made by the Royal Commission for Reform of the Poor-law in England are considered favourably. The gist of the report consequently is the recommendation of the establishment of a Public Assistance Authority to take over the work of boards of guardians, which will be abolished, and to control the Dispensary Medical Service, which it is proposed to turn into a proper county service with a county superintendent and bacteriologist.

MEDICAL MEN AND THE BUDGET.

WE are not a political journal, but when political proposals seem likely to bear hardly on the members of our own profession it is our duty to protest. And there is one tax which as it stands at present—and the clause in the Budget which levies this tax has already passed the Commons—bids fair to weigh heavily upon an overworked and underpaid class of medical men—namely, the general practitioner in the country. This tax is the impost of 3*d.* per gallon on petrol. One of the chief Government organs in its issue of April 30th remarked: "Private motor cars are always a luxury, and often an anti-social luxury." As regards cars used by medical men, they stand on exactly the same footing as the bicycle which many working men use to carry them *to and from their work. If the one is a luxury so is the* other. Both classes use mechanical methods of transit, first on account of cheapness, and secondly because by so doing they get a little more leisure than they otherwise would. Before the *advent of the motor-car* many general practitioners worked with horses from 14 to 16 hours per diem, but when they gave up horses and took to a car they were enabled to obtain some three or four hours more leisure than before. This may be luxury, but it is certainly not anti-social. The tax will press heavily upon such men as these. Take a concrete instance. In one district of the South-East of England are some 40 medical men, of whom at least 30 drive a car. The average net income of these men is from £600 to £700 per annum and the new tax will impose an extra burden upon them of from £5 to £15 yearly according to their mileage. In more scattered districts the burden will be far heavier. Many medical men in hilly districts in Wales and Yorkshire drive from 7000 to 10,000 miles a year and will have to pay over £20 in tax for their petrol. The rebate allowed to medical men in their car tax will practically make no difference, for as the duty stands at present a medical man pays a duty of two guineas for his car. In future a medical man driving a car under 16 horse-power, and we may say that hardly any general practitioner drives a more highly powered one, will pay exactly the same, that is to say one half of £4 4*s.* The medical man should at least be allowed the rebate on his petrol, which is to be allowed to motor omnibuses and motor cabs. For too long has the medical profession been made *the scapegoat of Governments.* Day by day new duties are imposed upon it without any corresponding pay, and at least in one case with a penalty attached if the new duty is not carried out. The recent Budget places a heavy tax upon many general practitioners, which is accompanied by a concession which is of no real value.

MEDICAL TREATMENT OF LONDON SCHOOL CHILDREN: THE LONDON COUNTY COUNCIL AND THE CLAIMS OF THE MEDICAL PROFESSION.

WE publish this week a synopsis of an interesting statement issued to members of the London County Council on the subject of the medical treatment of London school children (see p. 1343), and in another column (see p. 1347) will be found a strenuous letter from Dr. H. Beckett-Overy pointing out the risk that there is in the present circumstances of the medical profession being considerably exploited. We hope and believe that this risk is not so acute as Dr. Beckett-Overy seems to think, and we do not suppose for a moment that the chairmen and secretaries of the London hospitals, whether they agree with any proposals made to them by the London County Council or no, will come to any decision in the matter without a proper consultation with their medical staffs. Our information here is to an exactly opposite effect to Dr. Beckett-Overy's. As a matter of fact, the whole question *is at this moment before the authorities of the London* hospitals, and we are able to say that the just claims of the medical profession do not appear in the least likely to go unsupported. The matter will resolve itself, of *course, largely into the treatment of adenoids, deafness,* and of various forms of inadequacy of sight and dentition, and to a certain extent the little patients would in any circumstances attend the hospitals for relief, and with perfect right, for many of them belong genuinely to the class for which the voluntary hospitals were established and are maintained. Referring now only to those who are proper objects of charity, the question is really whether special clinics set up by the London County Council and staffed by the education medical officers should do the work, o whether the hospitals should do the work. It is perfectly clear that the London County Council has no right to get the work done for nothing, and we credit it with taking this view and with not desiring to exploit the medical profession. If school clinics are founded, as seems to be *the desire of the majority* of the special committee of the Council dealing with the subject, it will fall to the lot of salaried medical officers to manage such clinics, and payment on some scale or other will duly follow. But all the patients are not proper objects of charity, and here it seems *inevitable* that the general practitioner will have taken away from him a certain number of cases which he could well deal with, whether the hospitals arrange to do the work or whether it is done by school clinics. In some general practices the number of cases lost may be quite considerable. With regard to payments made to *hospitals by* the London County Council, there will be a difference of opinion as to their propriety. The hospitals ought to be paid, as a matter of abstract justice, because there is no reason why they should gratuitously relieve the burden of the London County Council by presenting it with the results of medical skill and service. But the difficulty presented by a voluntary charity staffed by unpaid officers accepting payment from the rates for work done seems almost insuperable. Such payment, while aggravating the difficult position of the general practitioner, is a large step towards that municipalisation of the hospitals for which we are not yet prepared, and which, if and when it comes, must bring with it the adequate payment of the medical staffs. There are some good arguments against the utilisation of the hospitals in addition to those which have already been made known to the London County Council in the circular statement. To mention one more only, the Council might demand representation on the governing bodies of the hospitals in return for its subsidies, and this demand would, we take it, be refused by even those institutions now favourable to the scheme. Arguments in support of the alternative scheme of school clinics must, however, be scanty, as we have no practical experience of their working in this country. But we cannot see that the institution of school clinics would remove patients from the care of the general practitioner any more than subsidized treatment at the hospitals. Of one thing we feel sure, that the various committees of the hospitals will debate these points thoroughly, and will recognise the extreme gravity of the issues raised. Whoever does the work for the London County Council ought to be paid, and the idea of using the honorary services of the medical staffs in return for a grant to hospital funds seems to us monstrous. Is it not a case in which the opinion of these staffs might be consolidated by some meeting among themselves?

---

[1] These recommendations were published at length in THE LANCET of Nov. 24th, 1906, p. 1460.

OUR BLEACHED DAILY BREAD.

IN our columns on March 20th and March 27th respectively two annotations appeared under this heading which, it has been suggested to us, require modification in view of a judgment delivered by Mr. Justice Warrington on April 28th in the case of the Flour Oxidizing Company, Limited, *v.* Hutchinson. Our notes had nothing whatever to do wittingly with this case, which is not alluded to in any way, and of the existence of which we had no knowledge; but we are informed that the statements made by Mr. E. F. Ladd and Mr. H. L. White in the *Chemical News* of March 19th, referred to by us, were made the subject of actual investigation in the action and that the evidence of Dr. A. P. Luff, Dr. W. H. Willcox, and Dr. W. D. Halliburton led Mr. Justice Warrington to the conclusion that the process, or some similar process, employed by the Flour Oxidizing Company, Limited, had no injurious effect on flour. Mr. Justice Warrington, after pointing out that the method employed by the Flour Oxidizing Company would render it less likely to be attacked by mites and other organisms, went on to say, relying on experiments made by Dr. Halliburton, "the result, in my opinion, of the whole of those experiments, taking them as a whole, is, that so far as the bread made from the flour is concerned, which is the important part, there is no substantial difference, in point of digestibility, between the bread made from the untreated flour and the bread made from the treated flour." Upon the question whether the flour had had imparted to it certain toxic qualities by the plaintiffs' process, Mr. Justice Warrington considered that the experiments of Mr. Ladd, to which we alluded in our annotation on March 27th, failed to prove this point. "Dr. Willcox and Dr. Luff," he said, "who are two of the most eminent men in their branch of the medical profession, have made experiments on rabbits with concentrated extracts of flour bleached under the plaintiffs' process, and they made those extracts following minutely the directions given by Dr. Ladd, and they have administered them to rabbits—a large number—have kept those rabbits under observation for many days after administration, and have observed no effect on the rabbits beyond temporary intoxication caused by the fact that the extract was alcoholic." His lordship added that he found no positive facts that the nutritive quality of the flour was deleteriously affected by the process.

THE NATIONAL LEAGUE OF PHYSICAL EDUCATION AND IMPROVEMENT.

THOUGH we who have our part in the complex civilisation of the twentieth century be in truth the heirs of all the ages of science and invention and philosophy, it is certain that our forefathers have not handed down to us the full endowment of their more ancient heritage. It is, for instance, a safe assertion that the Athenians of the fifth century before Christ held in far higher regard the physical culture of their sons and daughters than we in England to-day in spite of the boast of our national devotion to athletic pursuits, and in spite of our scientific knowledge of the principles upon which sanitation must be based. We do not, of course, mean that their death-rate was not more than ours (though their infant mortality was surely no greater), but that every family set up for itself an individual ideal of health unknown in modern England. The reason was, of course, that the Greeks were inspired with an æsthetic motive that would only be satisfied by the training of the human body in such a manner as to fit it for the honour due to the highest material expression of beauty, with the result that the Grecian form, perpetuated in Grecian marble, has been the wonder and the despair of generations of artists in far later centuries. And granting that the Greeks were powerless to protect themselves against the ravages of infectious disease, granting that the communal hygienic arrangements in the days of Pheidias were in no degree comparable to those of a modern city, still we believe that their intense love for physical perfection in a country where sunshine, fresh air, and good food were everybody's birthright produced a national result which is as unattainable by the modern social reformer as the great spirit of Grecian art is remote from the modern studio. But there is more than one road up most mountains, and if we cannot expect that an improvement will be effected in our national physique by an appeal to the nation's æsthetic perceptions, it is not too much to hope that it may be brought about by first adding to the nation's knowledge of the rules of health and disease, and then appealing to its common sense to apply them. Education, in a word, must be the spirit moving through the land to teach the masses of our people that what was good enough for their fathers in the matter of physical well-being is not good enough for them. Legislation and inspection may indeed afford the machinery for a faultless national hygiene, but it must remain ineffective in the main if in the tenement houses and cottages throughout the country there is not an intelligent appreciation of the reasons behind sanitary laws and of the great benefits which will accrue to those families that scrupulously obey them. Of recent agencies which have arisen for the diffusion of such knowledge, the National League of Physical Education and Improvement is pre-eminently active in promulgating the gospel of health. We have already announced the delivery of several lectures and addresses under its auspices, and now have to record the widening of its appeal at a Mansion

House meeting held at the end of April under the presidency of the Lord Mayor, at which such influential speakers as the Bishop of Ripon, Lord Halsbury, the Duke of Argyll, Sir Henry Craik, and Sir John Tweedy spoke in favour of the objects of the league, aims which are fairly summarised in its title. Resolutions were carried proclaiming the "imperative necessity for the provision of pure milk in order to lessen the appalling mortality that at present prevails among infants" (a resolution to which it will be remembered that Mr. John Burns is pledged to give early legislative effect); and proclaiming "that in the interests of the physical welfare of the coming generation provision of health visitors is of cardinal importance," a course which the league is urging upon local authorities; and "that physical education should be made compulsory in all schools, subject to proper medical supervision." These three resolutions embody a strong programme, and if adequate and widespread effect can be given to these alone by the league they would well justify its existence. We would repeat our advice that the league should make its first object the education of the people. It can do no greater service than to make fertile the soil to receive such legislative sanitary seed as may in the future fall upon it. It is true that many years have elapsed since Beaconsfield uttered his dictum that the nation's health should be amongst its statesmen's first duties, and we know that the health of our country is still a long way from occupying so prominent a position in our affairs of State. But when we think of what has been effected in sanitary reform during the last 50 years we have a great deal to be thankful for, and we repeat that when every child is taught how to keep healthy, and that to do so is a prime duty of citizenship, we may hope for a revival of the Grecian spirit that reverenced the perfection of the body only less than it abhorred its deformities.

APRIL AT HOME AND ABROAD.

THE month that has just elapsed was remarkable for its brilliancy in the United Kingdom and for its dryness over the greater part of southern Europe and the Mediterranean. It is very seldom that so great a quantity of sunshine distinguishes the month in this country, and according to the records since the observations began to be general 28 years ago there are only two Aprils with such a brilliant record. The first was in 1893, when the weather was really summer-like and almost entirely rainless, and the other occasion was in 1906. During both months the sunshine figures were about equal to those of the month under discussion over the major portion of England, but some localities have never enjoyed before such a bountiful supply of April sunshine. Among the number of these is London (Westminster), where the grand total of 220 hours exceeded the average by 106 hours, and also exceeded the averages for the summer months of June, July, and August. The midland counties and some northern cities were also remarkably bright, the total number of hours at Manchester, a place where the sun is so often obscured by smoky fog even when there is no cloud, amounting to 192 hours, while at Nottingham the month's record was 238 hours, a figure fully 100 hours in excess of the normal. Over the kingdom generally the temperature was about two degrees above the average, and the diurnal range usually small for the time of year. Very fine weather was also the rule over the Mediterranean region and the Spanish Peninsula, rainy days being extremely rare, and the sky generally almost free from cloud, while the temperature made a striking advance towards its summer figure. As is invariably the case at this time of year, Italy and all the southern parts of France were much warmer than the warmest spots in this country, and Paris, which during the winter months is nearly always colder than London, was very appreciably warmer, the mean warmth of the afternoon being as much as 6° greater. At Algiers the mean temperature of the daytime equalled the day average of June in London, while its nights were slightly warmer than the average night of the London July. The most agreeable weather of all was probably experienced at Madeira, where the maximum warmth of the days was never less than 63° and never greater than 68°. During more than half the month the maximum temperature was either 66° or 68°, and except on one day the period was entirely rainless.

—	Highest temperature.	Lowest temperature.	Mean maximum temperature.	Mean minimum temperature.	Mean temperature for month.	Mean diurnal range of temperature.	Number of days with rain.	Total fall in month.

ENDEMIC HÆMATURIA.

SINCE 1852, when Bilharz showed that endemic hæmaturia was due to the presence in the body of a special form of distomum, no doubt has ever been cast on the correctness of his demonstration, and the causal connexion of the hæmaturia and the organism has been acknowledged by all. A further problem, however, in regard to the disease has not yet been satisfactorily solved. This question is the mode of entrance of the bilharzia into the body. The generally received opinion is that it is taken in with drinking water, and makes its way into the blood-vessels and by the blood stream is carried to the urinary organs. One argument against this view is that monkeys and other animals which have been fed with free embryos have not become infected with the disease. This argument is of some weight, but too much stress must not be laid upon it. It is at least curious that the eggs have never been detected in the stomach. Dr. James F. Allen of Pietermaritzburg has had an extensive experience of the disease, for it is extremely prevalent in Natal, and he has held for some years the opinion that the organism *enters the body, not* by the mouth, but by the urethra and sometimes by the anus. In the present issue of THE LANCET (p. 1317) he makes a further contribution to the subject, and he claims that the symptoms demonstrate that the urethra is affected before the bladder, and the bladder before the kidneys. He holds that the entrance of the distomum occurs during bathing, and that its entrance is favoured by a long foreskin, as the water containing the worm then remains in contact with the meatus sufficiently long to allow the worm to enter the urethra. Dr. Allen finds that if precautions be taken to prevent the entrance of the worm the disease does not occur, or if the patient has already become infected further infection is prevented. We would not venture to express a decided opinion on so difficult a matter, but it cannot be denied that there appears to be some ground for Dr. Allen's contention, though he has not yet succeeded in proving his thesis. Further observations and further experiments are required before this important question is conclusively settled.

AERIAL NAVIGATION: PAST, PRESENT, AND FUTURE.

LITTLE did Horace imagine when he moralised over the ill-inspired daring of a Daedalus who essayed to "wing the blue depths"—

"Pennis non homini datis,"

or when he dwelt on the vain ambition of an Archytas—

"Aërias temptasse domos,"

that a few miles out of Rome, on the way to his beloved Tibur, an airship would one day be seen describing all manner of liquid curves at an altitude of many hundred feet from the ground, and that having covered 60 *millia passuum* (Roman miles) it would descend triumphantly to the greensward from which it took flight, bearing on board a crew of distinguished passengers to receive the congratulations of a crowd of Quirites on their having, after careering through the heavenly spaces, touched *terra firma* in safety once more! Such, indeed, was the spectacle afforded in the past Easter week at Rome by Mr. Wilbur Wright who has recently visited England—a spectacle that set the thousands of eye-witnesses athinking on the potentialities of a new form of locomotion, whether in the interests of peace or in the interests of war. Not for the first time has aerial navigation been an accomplished fact, as M. Fraikin, in the *Revue Ebdomadaire*, has just reminded us. But the eighteenth century flights to which he refers were quite wanting in the means of directing and controlling movement, above all in the "staying-power," so successfully realised by the American mechanician. Leaving the combatant or strategic aspects of the now fairly launched airship to the military and naval experts of the rival nationalities, we may pause for a moment to contemplate the resources it offers to the invalid requiring change, whether climatic or atmospheric, or in quest of new conditions in the matter of warmth or coolness, or, hygienically considered, of escape from the unlovely, unwholesome neighbourhood of the crowded centres of population and industry. Some 15 years ago THE LANCET opened its columns to suggestion and discussion in this sense, and if the subject dropped before getting beyond the stage of a "pious opinion," its being started at all was symptomatic of a dim presentiment that science was ripe for some such new departure as that of which Mr. Wilbur Wright is the "hero and eponymus." Even the captive balloon, it was then maintained, might have its uses in vouchsafing the invalid an interval of respite "far from the madding crowd" or in forming a variety of "rest cure" not unwelcome to many a valetudinarian who had exhausted the traditional "alteratives" in favour with such cases. All this, we repeat, is only referred to as showing in the not distant past a dim consciousness that an unexplored, unattempted field of therapeutic utility was awaiting the advent of the mechanician ingenious enough and persevering enough to overcome obstacles hitherto held to be insurmountable, and to prove once more the truth of the Baconian induction that there is no limit to what human inventiveness can achieve when working, with the due equipment, on the lines of experimental science.

TRANSMUTATION OR IMPURITY?

THE theory of electrons, which would teach that all elements are fashioned out of one prime material, and that the form which the element ultimately takes depends on an amount of energy represented by more or less electrons, is so attractive that fresh facts which appear to support this view will be welcomed. An experiment described in the *Chemical News* of April 30th at first sight seems to supply some evidence of the resolution of one element into another by exposing it to the influence of high potential discharge. The results are communicated by Mr. Bayard G. Cobb of Dawson City, Yukon, Canada. Minute precautions were first taken to prepare an absolutely pure amorphous gold by methods well known to chemists. The pure gold was then placed in a tube furnished with rubber corks carrying electrodes connected with the terminals of the high tension windings of a 10-inch induction coil. A current was passed and a spark was discharged through the tube containing the gold for half an hour, at the end of which time the amorphous element was withdrawn and examined. The gold showed radio-active properties, but, more important still, on dissolving it in aqua regia and examining the solution, copper was undisputably found to be present. The experiment was repeated four times with a similar result every time. Another tube was fitted up, but this time it was made partly vacuous. "On the passage of the current for three-quarters of an hour, subsequent solution, and analysis the presence of a copper salt was shown in even more marked degree." The electrodes employed were pure platinum. If this experiment succeeds in other hands (and the details and manipulation are so obviously simple that many other investigators will be ready to try it), an easy and striking method of demonstrating the degradation of one element to another, or a re-arrangement of electrons, is afforded us. The suggestion of impurity as an explanation of the presence of copper in the gold is irresistible, though perhaps ungenerous. Still, Mr. Cobb has promised to continue the work in order to clear up this portentous point. After all, there is no reason why, if the theory of degradation is true, we should not, with the great electric energies at our disposal, be able to establish the principle, even if it is only on a small scale. It is the small scale, however, which makes difficult the task of eliminating the question of impurities. In any case, the evidence so far points only to transmutation downwards and not upwards having been achieved; and the latter eventuality would be more exciting to fiscal circles.

THE TREATMENT OF NEURALGIA AND FACIAL SPASM BY INJECTIONS OF ALCOHOL.

IN the present issue of THE LANCET we print an interesting article by Dr. Wilfred Harris on the Alcohol Injection Treatment for Neuralgia and Spasm. Dr. Harris has been largely responsible for introducing the valuable procedure which he describes into this country, and his paper will be read with profit. The method of treating trigeminal neuralgia by the injection of a few minims of 75 or 80 per cent. alcohol into the sheath of one or other branches of the nerve has now passed beyond the experimental stage and is meeting with increasing favour. Injection of the seventh nerve for facial spasm has been the natural sequence, and Brissaud, Sicard, and other French physicians have already recorded satisfactory results. The disadvantage of the method lies in the production of facial paresis or paralysis, but this is a transient phenomenon. In very mild cases no doubt the possibility of paralysis does not [illegible] the adoption of the injection method, but for [illegible] cases it is a procedure both easy and effective. Dr. Patrick of Chicag[illegible] *Mental Di*[illegible] treated in t[illegible] months. I[illegible] cure has been the result, the facial paralysis subsequent on the injection having entirely vanished in the course of some months. The third case was unsuccessful; "needless to say (comments the modest physician), the failure was not due to the method but to the operator." The technique is simple, but the details must receive minute attention. Under aseptic precautions an ordina[illegible] is introduced immediately in[illegible] to reach the nerve at its exi[illegible] foramen. By this means 20 minims of 75 per cent. alcohol, containing a little cocaine, are injected into the nerve, and success is indicated by instantaneous cessation of the spasm and development of complete peripheral facial paralysis in the course of a few moments. That precautions are necessary is, of course, obvious, for it cannot be pleasant, as Dr Patrick narrates, to record not merely an utter failure to produce relief, but to hear that some days later the patient has an auditory meatus full of bloody pus. It is true that in the case where this occurred the mischief soon cleared up, but the spasm remained uninfluenced. Dr. Harris in his paper, which is mainly concerned with trigeminal neuralgia (see p. 1310), mentions that he has treated three cases of facial spasm by injecting 80 per cent alcohol around the nerve. This causes slight paresis but immediate cessation of the muscular spasms. If the alcohol is injected into the nerve facial paralysis results, although this disappears in from two to three months. In all operations of this kind Dr. Harris points out the necessity for the strictest asepsis

THE EXHIBITION OF THE ROYAL ACADEMY.

THE 141st exhibition of the Royal Academy of Arts was thrown open to the public on May 3rd, and the public will find, as it is beginning to consider should be the case, that Mr. Sargent has produced the most striking work in the exhibition. But it is not on account of his portraits, admirable as is No. 179, "The Earl of Wemyss," that we say this, but on account of two other pictures, the one (No. 446) a decorative design entitled "Israel and the Law," and the other (No. 496), called "Cashmere," a little procession of women robed in soft greyish drapery. Of portraits of particular medical and scientific interest there is No 89 by Sir Luke Fildes of Sir William Allchin, a good picture; No 246, by Mr. Solomon, of Dr. Ludwig Mond; and No 424, of Dr. Charles Drage, by Miss S. C. Harrison. Other striking portraits are No. 60, of Mrs Greiffenhagen, by Mr Maurice Greiffenhagen; No. 80, by Mr. J. J. Shannon, of the Misses Tennant; No 109, by Mr. Melton Fisher, of the three Misses Lyster; No. 293, by Mr. J H. F. Bacon, of Sir Charles Santley; Nos 404 and 408, of Lady Binning and the Countess of Ronaldshay respectively, by Mr. George Henry; No. 435, by Mr. Charles Sims, of Mrs. Harold Phillips; and No. 678, a portrait, amazingly clever, scarcely beautiful, and blatant in colour, by Mrs. A. L. Swynnerton, of Mrs Fenwick. The portraits this year are a feature of the Academy display. Of other pictures which will attract attention we may mention No. 3, "The Night Piece to Julia," and No. 528, "Ephemera," by Mr. Sims; Mr. Arnesby Brown's No. 19, "The River"; Mr. G. Clausen's No. 25, "The Interior of an Old Barn"; Mr. Chevallier Taylor's "The Anniversary," No. 35; Mr. MacWhirter's four antithetical landscapes—namely, No. 41 [illegible] Harbour at Genoa" at evening and [illegible], and Nos. 102 and 106, "The Riviera" looking towards Italy and France respectively; and Mr. A. [illegible] No. 296, "A Bacchante." Mr. Waterhouse, [illegible]d Mr. Draper, No. 198, have each sent their [illegible] of Lamia. Mr. Waterhouse's "Lamia" is his [illegible] beautiful young woman depicted "fair, on a sloping green of mossy tread" with her serpent skin in her lap, "vermilion spotted, golden, green, and blue." Mr. Draper's "Lamia" is also in the woman state and has the old serpent skin around her all transparent and colourless, but, like poor "Elsie Venner," she shows her serpent character in her narrow forehead and her curious eyes. Further, she apparently has an [illegible] Draper's other picture, No. 206, [illegible] is somewhat of a puzzle. Ulysses is represented tied to the mast and his eyes are gazing at something far away. The ship is invaded by three charming young women, one of them a mermaid, who have their mouths open as if they were singing, but Ulysses is not looking at them Are they the sirens or are they sea nymphs who have come to help him and his crew? Any way, the picture is well worthy of notice Mr. George Harcourt, whose very clever picture, "Supper in Summer-time," was a feature of last year's Academy, has another sound and adroit piece of work this year, No 218, "The Tracing," and Mr. Campbell Taylor sends a notable study in black, white, and grey, No. 322, called "Bedtime" Mr. F. Sydney Steel has a good picture which is unfortunately skied, No. 396, showing "Shetland Ponies in a Storm." We feel sure that Mr. F. O. Salisbury in his skilful picture, No. 323, "The Quest of St. George," should not have dressed his ecclesiastics in the vestments of the Western Church and those, too, of quite a late pattern. In Gallery IX. are two delightful little landscapes, Nos. 484 and 574, by Mr. Albert Goodwin; and in Gallery No. XI. is one of the best pictures of children in the exhibition, entitled "Us," by Mr. Keith Henderson, No. 701.

THE HEAT PRODUCED BY THE HEART'S CONTRACTION.

THE heart by its contraction produces heat as well as the mechanical work necessary for purposes of maintaining the circulation. Professor Sigmund Exner, in a paper read before the Royal and Imperial Society of Physicians in Vienna, and recorded in the *Medizinische Blatter* of April 10th, discussed the means by which the heat so produced is dispersed and the heart prevented from being overheated. He pointed out that whereas in cold-blooded animals the heart is often at a distance from the lungs and in many of them is surrounded by the liver, in warm-blooded animals it is closely invested by the lungs, and in birds by the air sacs He has calculated that in man about 322 Calories of heat are abstracted from the body daily by means of the lungs, 80 being employed in warming the expired air and 242 in saturating it with water vapour. He estimated the heat produced by the heart at about 70 Calories daily, and he suggested that this was in part given off to the surrounding organs, especially the lungs. Some experiments by Yoshimura, in the physiological laboratory at Vienna, by means of thermo-needles, showed that the walls of the ventricles were about half a degree warmer than the lungs and that the farther the spot investigated was from the heart the cooler its temperature was The wall of the left ventricle showed a higher temperature than the blood contained in it, and with the heart exposed the difference might be as much as two degrees. The blood in the left ventricle was found to be lower in temperature than that in the right, which is attributed to the fact that the blood coming to the right side is brought from regions in which active processes of oxidation are in progress. Professor Exner stated that the heart gives off one-fifteenth to one-tenth of the heat produced by it from its surface, and that if this loss be prevented by surrounding the heart with a non-conductor its temperature rises. The right ventricle is not surrounded by the lungs, and owing to its thinner walls and to the comparatively small amount of work it has to do—viz., only about one-seventh or one-eighth of that of the left—the importance ot its cooling is less. Dr. Max Herz criticised Professor Exner's conclusions, and suggested that the blood circulating in the coronary vessels was of much greater importance in abstracting the heat produced by the heart's contraction than the loss from the surface to the lungs. It is obvious that the heat produced by the heart's contraction must be rapidly dissipated, and it is probable that both factors play a part.

RIGHT AND LEFT HANDEDNESS.

Dr. James Taylor has sent us a suggestive note on the subject of right and left handedness, in which he first reminds us that the reason why one man is right-handed and another left-handed, or rather why 98 men out of 100 are right-handed and the remaining two are left-handed, has never been satisfactorily explained. He proceeds to disclaim any intention at present of attempting the missing explanation of this fact, merely wishing to set out clearly the existence of certain conditions which, so far as he is aware, have not been clearly recognised. Pure right-handedness and pure left-handedness we all know, but there are two other varieties of "handedness" in which there seems to be a mixture of the two conditions. The purely right-handed man uses his *right* hand for all purposes for which one hand is used, to throw a stone, to cut bread, to play lawn tennis, or to use a fencing foil. The purely left-handed man uses his *left* hand for all those purposes. (In reference to this, writing must be left out of account, for no boy or girl, no matter how left-handed he or she may be, is ever allowed to learn to write with the left hand.) To put it briefly, the really right-handed man uses his right hand for all single hand actions; the truly left-handed man uses his left hand for all similar single hand actions. When, however, Dr. Taylor continues, as in certain games like cricket and golf, and also in swinging an axe or a two-handed hammer, both hands are used, we sometimes find that the man with true right-handedness for single hand actions—e.g., lawn tennis and bowling—bats left-handedly and plays golf left-handedly. And, conversely, we frequently meet with the man who plays lawn tennis with his left hand and bowls with his left hand and yet bats and plays golf right-handedly. So that four different classes can really be distinguished: (1) those who are right-handed for single-handed actions—e.g., lawn tennis, bowling, fencing, &c.—and also for two-handed actions—e.g., batting at cricket and golf; (2) those who are left-handed for single-handed actions like lawn tennis and bowling, and who also bat and play golf left-handedly; (3) those who for single-handed actions, like bowling and lawn tennis, use the right hand and yet bat and play golf left-handedly; and (4) those who for single-handed actions, like bowling and lawn tennis, use the left hand and yet play golf and bat right-handedly. Dr. Taylor claims that no one at all familiar with the subject will dispute the existence of those four classes, although in the present note he does not inquire how they arise. The explanation of the origin of the third and fourth classes involves a problem of particular interest. He suggests that its solution would be helped by an inquiry directed to discover whether individuals in these two classes of what we may call "mixed-handedness" are as expert in the double-handed games as those in the classes of what we may call "pure-handedness." *A priori* he would scarcely expect them to be, because in these instances the 'naturally dominant hand is reduced to a subordinate position' in the double-handed actions. And he would expect those to excel in the double-handed game in whom the dominant hand is allowed to have its natural position of dominance. The point which is thus raised deserves examination by psychologists and physiologists alike, and we hope that Dr. Taylor may find opportunity to throw light upon the existence of "mixed-handedness" in a further communication.

MILK, GUINEA-PIGS, AND THE LONDON COUNTY COUNCIL.

AT the meeting of the London County Council on May 4th the Public Health Committee reported that 1025 samples of milk had been examined under the General Powers Act of 1907 for the purpose of ascertaining whether tubercle bacilli were present. It had been found that the subcutaneous injection of material from 167 samples into guinea-pigs caused their death from some acute infection, the nature of which was not ascertained. These deaths made it impossible for the Lister Institute which had carried out the investigation to report whether the samples were tuberculous, but it was willing to continue its investigations for at least 12 months at a cost of £330, and the committee recommended that this expenditure should be sanctioned. The recommendation was discussed in connexion with the annual estimates which contained an item in respect of the proposed expenditure. Mr. Whitaker Thompson moved the deletion of the estimate. He doubted very much whether the Council had power to subsidise the Lister Institute in order that that institution might make experiments upon guinea-pigs. He found a seconder in Mr. Felix Cassel, K.C. Mr. Gilbert Johnstone, chairman of the Public Health Committee, said that on grounds of common-sense the experiments must be made. Some acute infection, the nature of which they did not quite know, was present in a considerable percentage of the samples. It might be that there was a worse danger in the milk than tuberculosis. The committee felt that so grave a question must be dealt with as soon as possible. The amendment was lost and the estimate was approved. We are glad that the common-sense of the Council prevailed in this matter, as it is obviously of great public importance that further investigations should be carried out. At the same time, some explanation of the circumstances seems advisable to allay anxiety upon a report which appears very serious on the face of it. We understand that the reason why the early death of the guinea-pigs prevented the detection of tuberculous milk was that at the Lister Institute the result of a diagnostic inoculation is only pronounced negative when the animal has survived three weeks without developing any signs of tuberculosis, and that in these experiments the guinea-pigs died before this period of incubation had passed. The infection to which the guinea-pigs succumbed was of a somewhat complex nature which needs further research before a definite pronouncement can be made upon it, but in the meantime it should be pointed out that the inoculations were made with a highly concentrated centrifugalised deposit and that deductions should not be drawn too hastily from the alarming results of these experiments upon guinea-pigs to the probable effect upon human beings of the consumption of the milk from which the material for inoculation was derived. At the same time it is essential that all possible information should be obtained upon the substance or substances in the milk which killed the guinea-pigs, and the Council could not have acted more wisely than it has in leaving the investigation in the hands of the Lister Institute of Preventive Medicine.

INSPECTION OF FOREIGN MEAT.

SOME years ago the Netherlands Department of Agriculture arranged a special system of inspection of meat intended for export from Holland to Great Britain and other countries. The services of Government veterinary inspectors were made available at the slaughter-houses concerned, a code of regulations was drawn up to guide inspectors as to condemnation, and an official label with an identification number was attached by a lead seal to each carcass which passed the inspector. The system was inquired into by the Local Government Board, and recognition was given to the official label in the regulations made by that Department last year on the subject of foreign meat The Dutch exporter whose animal was condemned by the inspector in Holland could, however, still send it to the British market without the official label, and in the case of pigs, which are mainly in question, many of the carcasses brought into British ports have in the past been uncertified.' It is satisfactory, therefore, that the Netherlands authorities have now taken the further step of extending their meat inspection laws so as to provide that no fresh meat intended for export to the United Kingdom is in future to be shipped unless it has been inspected and officially marked as being in sound condition and free from disease. In the case of pork the term disease is understood to include tuberculosis in any degree. The Local Government Board has now issued a circular to port sanitary authorities (Foreign Meat, No. 4, of April 29th) notifying this change in the system of Dutch "official certification." The circular also deals with other matters relating to inspection of imported meat. Attention is drawn to frozen livers, kidneys, plucks, and other organs which are frequently imported in masses moulded to the shape of the box or bag containing them. The port sanitary authorities in London and elsewhere have recently caused samples of these packages to be thawed out, and have in several cases found their contents objectionable on account of the presence of disease or of decomposition in the centre of the mass. The circular insists on the necessity of the individual organs being separately frozen in the country of origin, and arriving in such a way that on opening the package the organs retain their natural shape and permit of individual examination. Separate freezing of small organs like sheeps' kidneys can be dispensed with only if the kidneys are packed in shallow boxes so that the frozen contents consist of not more than two layers of kidneys not tightly pressed together. In the case of packages containing frozen livers and lungs or "plucks," the circular states that it is specially desirable with a view to detection of disease conditions that the ordinary examination made of a consignment at the port of entry should comprise thawing out specimen boxes, even when the organs have been separately frozen. In THE LANCET of Feb. 13th, p. 475, we laid stress on the need for strictly applying the powers of the Food Regulations Act so as to stop the importation of this highly perishable form of meat in large frozen masses which are incapable of inspection or examination. It is satisfactory to find from this circular that the Local Government Board has decided that all frozen "offal" must in future be imported in such a way that its suitability for food can be ascertained when it arrives at British ports.

TUMOURS IN THE REGION OF THE HYPOPHYSIS CEREBRI.

IN the *Review of Neurology and Psychiatry* for April Dr. Purves Stewart has published a series of four cases of pituitary tumour, in which the diagnosis has been corroborated either at operation or post mortem, and these cases present certain features of interest. One of the chief points to be noted is that the general signs of intracranial pressure are relatively slight. Headache is often absent, vomiting is rare, and optic atrophy of primary nature, rather than optic neuritis, is to be expected. The occurrence of primary optic atrophy is so frequent as to be of considerable value in framing a diagnosis. In no one of the four cases was acromegaly present in any degree, although in two the symptoms of tumour were of several years' duration, a fact which accentuates the truth of the remark that the causal relation between that disease and lesions of the pituitary body is very far from being clearly established. The classical visual signs of chiasma lesion, in the shape of bilateral hemianopia, or of blindness of one eye with temporal hemianopia of the other, were present in three of the cases, and are of the utmost diagnostic importance. In the other case the patient's mental condition was such as to prevent any examination of his visual fields being made. One feature which is brought out very distinctly in all the cases is the remarkable drowsiness of the patient. It is usually intense and often paroxysmal, lasting for hours, days, or weeks at a time. This pathological drowsiness in two of the cases showed curious intermissions; the patient was more or less constantly asleep in one instance, but suddenly had a lucid interval, during which he woke up and made a perfectly sensible will. The explanation of this symptom is still to seek. Evidence adduced to show that normal sleep is associated with a special internal secretion of the pituitary body is far from convincing. Perhaps it is the result of upward pressure on the third ventricle, or of cerebral anæmia produced by compression of the arteries of the circle of Willis. There can be no doubt of the frequency of loss of the menstrual function in women and of the genital function in men in association with disease of the pituitary body. The condition of so-called "pituitary eunuchism" has been noted in a large proportion of pituitary tumours, whether accompanied by acromegaly or not, and in both sexes this diminution of sexual activity is often associated with a tendency to an increase in the development of fat on the body. From the surgical point of view increased attention, more particularly in London and in Vienna, has been given to the question of operative interference in these cases, and successful results have been reported. In the *Johns Hopkins Hospital Bulletin* for April, however, Dr. Redford and Dr. Cushing raise the all-important question whether the pituitary gland is essential to the maintenance of life, and from a series of experiments they confirm the statement of Paulesco that total extirpation of the gland proves fatal. They consider, therefore, that surgical interference must be limited to removal of the tumour where it implicates the gland, or partial hypophysectomy in cases of hypertrophy of that structure.

A TELEGRAM from the Governor of Mauritius to the Secretary of State for the Colonies states that one case of plague with one death was reported during the week ending April 29th, and a telegram from the Governor of Hong-Kong, also received at the Colonial Office, states that seven cases of plague with seven deaths were reported during the week ending May 1st.

IT is proposed to present at the Twelfth International Congress on Alcoholism, to be held in July, 1909, in London, Mackey, M.D. Birm.; Percy Whittington Saunders, B.A., M.B. Toronto, L.R.C.P.; Henry Charles Gustavus Semon, M.A., M.B. Oxon., L.R.C.P.; and Arthur Stanley Woodwark, M.B. Lond., L.R.C.P.

Licences to practise physic were granted to 91 gentlemen who had passed the necessary examinations.

The following communications were received:—1. From the Board of Trade, March 26th, on Beri-beri, in continuation of previous correspondence in 1908. The matter was referred to the Standing Committee on Beri-beri. 2. From Dr. Raymond Crawfurd, asking permission to photograph the portraits of Sir Charles Scarburgh and Sir Edmund King in possession of the College. Permission was granted. 3. From Mr. Leverton Harris, M.P., asking permission to photograph the portraits of Dr. Cadogan and Sir G. Baker in possession of the College. Permission was granted.

The PRESIDENT announced that he had nominated Dr. S. H. Habershon to represent the College at the 350th anniversary of the foundation of the University of Geneva to be held in July next, as Dr. W. Pasteur would be unable to attend.

The PRESIDENT also announced that he had nominated Dr. E. I. Spriggs as one of the delegates of the College on the committee appointed to confer with the delegates of London University as to degrees for London medical students.

Sir William Allchin was elected a representative of the College on the Senate of the University of London.

The by-law for the admission of women to the examinations of the College for qualifications was enacted for the second time.[1]

Dr. W. P. Herringham was elected a representative of the College in the Court of Governors of the University of Sheffield. The thanks of the College were accorded to Dr. F. T. Roberts, the retiring representative.

The quarterly report, dated April 23rd, of the College Finance Committee was received and adopted.

A report from the committee of management dated March 22nd was received and adopted. The report dealt with the following subjects: 1. A revised syllabus of the subjects for both parts of the examination in public health was adopted. The syllabus will come into force at Jan. 1st next. 2. The report of Dr. Norman Moore, the visitor to the examinations of the Egyptian Medical School for the year 1908, was considered satisfactory in every respect. The thanks of the College were accorded to Dr. Moore for his services. 3. (*a*) The committee recommended that the Grammar School, Cheltenham, which has been visited by a member of the committee and reported as fulfilling the requirements of the Board, be added to the list of institutions recognised by the Examining Board in England for instruction in chemistry and physics. (*b*) The committee recommended that the Merchant Taylors' School, which is already recognised for instruction in chemistry and physics, be also recognised for instruction in biology.

The quarterly report of the examiners for the Licence on the results of the January examinations was received and adopted.

Books and other publications presented to the library during the past quarter were received and the thanks of the College were returned to the donors.

The PRESIDENT then dissolved the Comitia.

THE
SIXTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

WE have already in various annotations called attention to many of the arrangements for the approaching International Congress of Medicine at Budapest, and we print below a recapitulation of some of this matter with some added information which should prove useful to members of the profession who intend to be present.

The sittings of the Congress will be held from August 29th until Sept. 4th under the patronage of King and Kaiser Francis Joseph. His Majesty has named as his personal representative H.R.H. Prince Joseph. The national committees comprise the most notable scientists of signatory countries. Over a thousand communications have been sent in up to the present time from every part of the world. The Governments, magistrates, universities, and academies have already appointed their delegates. The business will be transacted in sectional and general sittings, and in the latter the representatives will hear addresses on topics of general interest tending towards the uniting of the nations in scientific work. The Hungarian Government, the legislature, the city of Budapest, and especially its scientific societies, are supporting the endeavours of the organising committee generously.

The Regulations of the Congress.

1. The day of opening is August 29th, and the day of closing is Sept. 4th.

2. The aim of the Congress is purely scientific.

3. Members of the Congress shall be all medical practitioners who have paid the membership fee, and who are accepted as members on the recommendation of their national committees or of the executive committee.

4. The membership fee is 25 crowns (about one guinea).

5. Wives and daughters of members pay half of this fee, which will entitle them to all the advantages offered to members by the railway companies. Such fees are to be sent to the treasurer, Dr. Elischer, Budapest VIII., Eszterházy Utcza 7, accompanied by a card and a note designating which section of the Congress the sender desires to join.

6. Members shall enjoy all the advantages of the Congress and shall receive the general volume of the proceedings of the Congress and also the special proceedings of his selected section.

7. The sectional classes of the Congress will be as follows: (1) Anatomy, Histology, and Embryology; (2) Physiology; (3) General and Experimental Pathology, Pathology (Physiological and Chemical); (4) Microbiology (Bacteriology) and Pathological Anatomy; (5) Therapeutics (Pharmacology, Physical Methods, and Balneology); (6) Internal Medicine; (7) Surgery; (8) Obstetrics and Gynæcology; (9) Ophthalmology; (10) Pediatrics; (11) Neurology; (12) Psychology; (13) Dermatology and Venereal Diseases; (14) Urology; (15) Laryngology, Disease of the Nose; (16) Otology (this section forming also the Eighth International Otological Congress); (17) Stomatology, Dentistry; (18) Hygienics and the Study of Immunity; (19) Forensic Medicine; (20) Military and Naval Sanitation; and (21) Tropical Medicine and Shipping Surgery.

8. The arrangements of the Congress are in the hands of an organising committee and of an executive committee.

9. The Congress will hold two formal sittings, which will form the opening and the closing ceremonies, at which only those appointed by the organising committee and nominated by the State representatives will speak. At the opening ceremony the organising committee will, after the usual addresses, proclaim the list of the honorary presidents of the Congress, and at the closing ceremony it will announce the place of the next Congress, which will be decided by a special committee sitting on the third day of the Congress. This committee will consist of the presidents and secretaries of the national committees and the president and chief secretary of the Sixteenth International Congress. The honorary presidents of the single sections will be elected at the opening sitting.

10. The last day for the notification of papers will be May 15th. Communications notified after this date will be put upon the programme only if time will allow.

11. Members have the right of attending other sections besides those to which they belong.

12. The speeches and addresses delivered at the opening and closing ceremonies will be printed at full length in the proceedings.

13. The time spent in delivering a communication shall not exceed 20 minutes, no speaker shall spend more than 10 minutes in a contribution to the discussion, and the reply of the opener shall not exceed 10 minutes.

14. At all the sittings the English, French, German, and Italian languages may be used by speakers.

The Central Committee of the Congress.

The names of the foreign honorary presidents will be proclaimed at the opening festivity. The following officials have been already appointed:—Honorary President of the Congress: Baron Frederik Korányi; President: Koloman Müller; Chief Secretary: Emil Grosz; and Treasurer: Julius Elischer.

Ladies Committee:—President: Mme. Professor Arpád

---

[1] THE LANCET, April 10th, 1909, p. 1069.

Bokay; Vice-Presidents: Mme. Professor Emanuel Herczel and Baroness Alexander Korányi. The members of the ladies committee number about 100. The Executive Committee consists of about 50 members. The National (Hungarian) Committee consists of about 300 members. The Reception Committee consists of 25 members. The Financial Committee consists of 15 members.

The Foreign Committees of the Congress.

The following are the officials of the various National Committees:—

England.—President: Dr. F. W. Pavy, London; Secretaries: Dr. Clive Riviere and Mr. D'Arcy Power, London.

Germany.—President: Geh. Med. Rat. Professor W. Waldeyer, Berlin.

United States of America.—President: Dr. John H. Musser, Philadelphia.

Austria.—President: Hofrat Professor A. von Eiselsberg, Vienna.

France.—President: M. le Professor Landouzy, Doyen de la Faculté de Médecine, Paris.

Spain.—President: M. le Professor Tallian Calleja y Sánchez, Madrid.

Egypt.—President: M. Armand Ruffer, President of the Egyptian Sanitary Quarantine Council, Alexandria.

Canada.—President: Professor Alexander MacPhedran, Toronto.

Italy.—President: M. le Professor Guido Baccelli, Rome.

Japan.—President: Professor S. Kitasato, Director of the Institute for the Research of Infectious Diseases, Tokio.

The Plenary Sittings of the Congress.

There will be six plenary sittings dealing with the following subjects. Dr. G. Baccelli (Rome): On Heroic Medicine. Dr. E. F. Bashford (London): On Cancer. Dr. M. Gruber (Munich): Vererbung, Auslese und Hygiene (Inheritance, Selection, and Hygiene). Dr. R. Kuttner (Berlin): Über das ärztliche Fortbildungswesen (On the Post-graduate Instruction of Medical Men); this address will be held under the auspices of the central committee of Prussian Post-graduate Instruction. Dr. A. Laveran (Paris): La Pathologie Exotique (Tropical Medicine). Dr. T. Loeb (Berkeley): Artificial Parthogenesis and its Bearing upon the *Physiology and the Pathology of the Cell.* The place and date of these sittings will be published in the journal of the Congress. At these sittings ladies will be admitted to the general meetings of the Congress.

General Arrangements.

For the benefit of the Congress the organising committee has made arrangements with the General Post Office of Budapest to send the letters of foreign members to the office of the Congress if nc [illegible] The telegraphic address will be [illegible] In our last two issues we have [illegible] of the arrangements made for lodgings and excursions for members of the Congress.[1]

MEDICINE AND THE LAW.

Action Against a Dairy Company for Selling Milk Containing Boric Acid in Breach of a Warranty.

AT the Croydon county court judgment was given recently by his honour Judge Harington in an action heard by him in February, in which the plaintiffs, Mr. Harold Bentley and [illegible] him as her next friend, claimed [illegible] Wraight, Dumbrill, and Co., [illegible] Mr. Bentley for the use of his [illegible] into a verbal contract with the [illegible] rough their agent at Mitcham, a [illegible] he supply of nursery milk free [illegible] dulteration for the consumption of his child born in December, 1907. He had already ceased to deal with another dairy owing to the presence of boric acid in the milk supplied, and his express stipulation and the dairyman Hughes's promise that there should be none were not disputed. While the child was being fed with the defendants' milk she suffered severely from diarrhœa, loss of appetite, and loss of weight, and her father eventually consulted Dr. David Forsyth, who recommended him to have the milk analysed. It then appeared that the milk contained boric acid in the proportion of five grains to the pint, and when this was discontinued the child improved in health, after which the action was brought. Medical evidence was given on behalf of the plaintiffs by Mr. Bentley himself, Dr. Forsyth, Mr. E. Hinks, analyst to the Surrey county council, and others. On behalf of the defendants Mr. Felix C. Kempster gave medical evidence, and Mr. Hughes and other witnesses connected with the dairy denied absolutely the use of boric acid in the business or in connexion with the milk complained of. In giving judgment his honour stated that there were two questions for his decision: 1. Did the defendants or their agents adulterate with boric acid the milk supplied to Mr. Bentley? 2. If so, was the child's illness due to such adulteration? Dealing with the second question first, and saying that the answer must depend entirely on the conclusion to be drawn from the medical evidence, having regard to the history of the illness, he found that there was boric acid in the milk during the period following June 6th and that the child's illness was due to it. After reviewing the evidence as to the other question, he came to the conclusion that the preservative found its way into the defendants' milk before it left their premises and that they were responsible under their warranty. He assessed the damages at £11 1*s.* 6*d.*, representing the actual cost to the father, with £5 5*s.* for the child in respect of suffering undergone, and gave judgment for that amount with costs on Scale B. Mr. Bentley is to be congratulated on the result of his action and upon having discovered in time the cause of his child's illness. The case shows the danger arising from the use of boric acid, and the value of analysis as a safeguard even when assurance of the purity of the milk has been given.

Looking Back.

FROM

THE LANCET, *SATURDAY*, May 7th, 1831.

POISONOUS TABLE SALT.

The Council of Health of Nantz have found, after a most rigorous and extensive examination, that the *table-salt* of that city was free from the admixture of arsenic and the combinations of iodine which MM. Latour de Trie and Chevallier have detected in Paris. The Academie de Medecine have recommended the Government to order similar inquiries to be prosecuted in every department of France.

COMPOSITION OF OXALIC ACID.

M. Gay Lussac has succeeded in decomposing this acid by a moderate temperature, and he states it to be composed of six parts of carbonic acid, five of carbonic oxide, and one of the formic acid.—*Lancette Franç.*

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8423 births and 4569 deaths were registered during the week ending May 1st. The annual rate of mortality in these towns, which had been 17·1 and 15·8 per 1000 in the two preceding weeks, further declined to 14·5 in the week under notice. During the first four weeks of the current quarter the death-rate averaged 16·1 per 1000, while in London during the same period the mean rate was 15·6. The lowest recorded annual death-rates in these towns last week were 7·6 in Leyton and in Walthamstow, 7·7 in Burton-on-Trent, 7·8 in York, and 8·2 in Hornsey and in Handsworth (Staffs); the rates in the other towns ranged upwards to 20·2 in Preston, 20·6 in Sunderland, 22·3 in Middlesbrough, and 24·0 in Bootle. The 4569 deaths from all causes in the 76 towns last week showed a decrease of 414 from the number in the previous week, and included 462 which were referred to the principal epidemic diseases, against 593, 584, and 518 in the three preceding weeks; of these 462 deaths,

---

[1] THE LANCET, April 24th, p. 1192, and May 1st, p. 1264.

225 resulted from measles, 113 from whooping-cough, 39 from diarrhœa, 37 from diphtheria, 34 from scarlet fever, 13 from "fever" (principally enteric), and one from small-pox. The 462 deaths from these epidemic diseases in the week under notice were equal to an annual rate of 1·5 per 1000, the corresponding rates for the two preceding weeks being 1·9 and 1·6 per 1000. No death from any of these epidemic diseases was registered last week in Brighton, Tottenham, Norwich, Northampton, Huddersfield, or in 12 other smaller towns; the annual death-rates therefrom ranged upwards, however, to 3·7 in Wallasey, 3·8 in Bootle, 4·0 in Wigan, and 4·4 in Preston. The deaths from measles, which had declined from 438 to 265 in the six preceding weeks, further fell last week to 225, but caused death-rates ranging upwards to 1·7 in Salford, 1·9 in Tynemouth, 2·3 in Bootle, 2·9 in Wigan, and 3·3 in West Hartlepool. The fatal cases of whooping-cough, which had been 130 and 131 in the two preceding weeks, declined to 113 in the week under notice, the highest death-rates from this disease being 1·4 in East Ham, 1·5 in Smethwick, 2·0 in Stockport, and 3·5 in Preston. The 39 deaths from diarrhœa slightly exceeded the number in the previous week. The fatal cases of diphtheria, which had been 53, 47, and 48 in the three preceding weeks, declined to 37 last week, and included nine in London and its suburban districts, three in Portsmouth, three in Burnley, and two each in Manchester, Halifax, and Wallasey. The deaths from scarlet fever, which had been 47, 31, and 28 in the three preceding weeks, rose again to 34, and included 12 in London and its suburban districts, and six in Liverpool. The 13 deaths referred to "fever" corresponded with the number in the preceding week, the highest death-rate being 1·5 in Wallasey. One fatal case of small-pox was registered in Cardiff, but none in any other of the 76 towns. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had decreased from 2873 to 2219 at the end of the eight preceding weeks, had further declined to 2181 on Saturday, May 1st; 305 new cases were admitted during the week, against 256, 244, and 265 in the three preceding weeks. The registered deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 341 and 294 in the two preceding weeks, further declined to 232 in the week under notice, and were 73 fewer than the corrected average number in the corresponding week of the five years 1904–08. The deaths in London directly attributed to influenza numbered 32 last week, and were nine in excess of the corrected average number. The causes of 38, or 0·8 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in London, Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, Nottingham, and in 47 other smaller towns; the 38 uncertified deaths included six in Birmingham, six in Liverpool, and three in Preston.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 18·4 and 17·4 per 1000 in the two preceding weeks, further declined to 16·9 during the week ending May 1st. During the first four weeks of the current quarter the annual death-rate in these towns averaged 17·6 per 1000, and exceeded by 1·5 per 1000 the rate during the same period in the 76 large English towns. Among the eight Scotch towns the death-rates in the week under notice ranged from 13·0 in Greenock and 14·8 in Dundee and in Paisley to 17·2 in Edinburgh and 18·1 in Glasgow. The 605 deaths from all causes registered in the eight towns last week showed a decline of 15 from the number in the preceding week, and included 93 which were referred to the principal epidemic diseases, against 98 and 86 in the two preceding weeks; of these 93 deaths, 55 resulted from whooping-cough, 21 from diarrhœa, five from scarlet fever, five from diphtheria, five from "fever," and two from measles, but not any from small-pox. The annual death-rate from these diseases was equal to 2·6 per 1000 last week, or 1·1 per 1000 more than the death-rate during the same period from the principal epidemic diseases in the 76 English towns. The fatal cases of whooping-cough, which had been 58 and 46 in the two preceding weeks, rose again to 55 in the week under notice and included 34 in Glasgow, 11 in Edinburgh, and three each in Dundee, in Aberdeen, and in Paisley. The deaths from diarrhœa, which had been 18 in each of the two preceding weeks, rose last week to 24, of which eight occurred in Glasgow, five in Edinburgh, three in Aberdeen, two in Dundee, and two in Leith. The five deaths referred to "fever" included three from enteric fever and two from cerebro-spinal meningitis; all these deaths were registered in Glasgow, where three of the five fatal cases of scarlet fever and four of the five deaths from diphtheria also occurred. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 135 and 118 in the two preceding weeks, further declined to 99 in the week under notice, and were eight fewer than the number in the corresponding week of last year. The causes of 23, or 3·8 per cent., of the deaths registered in the eight towns last week were not certified; in the 76 English towns the proportion of uncertified deaths during the same week did not exceed 0·8 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been 27·7 and 24·5 per 1000 in the two preceding weeks, further declined to 22·0 in the week ending May 1st. During the first four weeks of the current quarter the death-rate has averaged 24·9 per 1000, whereas the mean rate during the same period did not exceed 15·6 in London and 17·6 in Edinburgh. The 168 deaths of Dublin residents from all causes during the week under notice were 19 fewer than the number in the previous week, and included 16 which were referred to the principal epidemic diseases, against 21 and 12 in the two preceding weeks. These 16 deaths were equal to an annual rate of 2·1 per 1000, the rate from the epidemic diseases during the same week being 1·7 in London and 2·6 in Edinburgh. Of the 16 deaths from these epidemic diseases in Dublin last week, 13 resulted from whooping-cough, two from measles, and one from scarlet fever, but not any from small-pox, diphtheria, "fever," or diarrhœa. The fatal cases of whooping-cough, which had been seven, 11, and six in the three preceding weeks, rose again last week to 13, and exceeded the number in any previous week of the year. The 168 deaths registered during the week under notice included 31 of infants under one year of age and 53 of persons aged upwards of 60 years, the corresponding numbers in the preceding week being 28 and 59 respectively. Eight inquest cases and four deaths from violence were registered, and 61, or 36·3 per cent., of the deaths occurred in public institutions. The causes of four, or 2·4 per cent., of the deaths in Dublin last week were not certified; in London all the 1300 deaths were duly certified, while in Edinburgh the proportion of uncertified deaths was 3·4 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Staff-Surgeon Norman Ireland-Smith has been placed on the retired list (dated March 23rd, 1909).

The following appointments are notified:—Fleet-Surgeon: W. E. Marshall to the *Achilles*, on recommissioning. Staff-Surgeon: J. D. S. Milln to the *Vindictive*, on recommissioning. Surgeon: W. G. M. Anderson to the *Scylla*, on recommissioning.

ROYAL ARMY MEDICAL CORPS.

Captain J. M. M. Crawford has been transferred to the Eastern Command from Lahore.

SPECIAL RESERVE

Royal Army Medical Corps.

The undermentioned Lieutenants are confirmed in that rank:—James N. McLaughlin, Robert T. C. Robertson, and Joseph G. McCutcheon.

TERRITORIAL FORCE.

Royal Field Artillery.

3rd West Riding Brigade: Surgeon-Captain Archibald

[illegible]

Royal Army Medical Corps.

1st London (City of London) Field Ambulance: Lieutenant Robert Ollerenshaw resigns his commission (dated March 4th, 1909).

6th London Field Ambulance; Walter Brock Parsons to be Lieutenant (dated March 16th, 1909).

3rd Northumbrian Field Ambulance: Abram Cockcroft Barker to be Lieutenant (dated March 17th, 1909). Mervyn Alexander Archdale to be Lieutenant (dated March 24th, 1909).

3rd West Riding Field Ambulance: Lieutenant Herbert G. M. Henry resigns his commission (dated March 31st, 1909).

2nd Wessex Field Ambulance: Lieutenant Fielding O. Whitmore to be Captain (dated March 3rd, 1909).

2nd London (City of London) General Hospital: Captain (Honorary Captain in the Army) Ernest J. G. Berkley to be Major (dated April 5th, 1909).

North Midland Mounted Brigade Field Ambulance: Arthur Charles Goodwin to be Lieutenant (dated Feb. 22nd, 1909).

3rd Northern General Hospital: Surgeon-Captain Arthur Mayers Connell, from the 4th West Riding of Yorkshire Royal Garrison Artillery (Volunteers), to be Major (dated April 1st, 1908). John Sinclair White to be Lieutenant-Colonel (dated March 5th, 1909).

For attachment to Units other than Medical Units.—Surgeon-Major Charles Lachlan Fraser, from the Unattached List, to be Major (dated Feb. 21st, 1909). Clarence Isidore Ellis to be Lieutenant (dated March 30th, 1909). Gerald Stephen Hughes to be Lieutenant (dated Dec. 2nd, 1908). Francis Ley Augustus Greaves to be Lieutenant (dated Feb. 17th, 1909).

DEATHS IN THE SERVICES.

Colonel Herbert Murray Ramsay, R.A.M.C. (T.F.) (late [illegible] on April 29th at Cotswold [illegible] took an active interest in [illegible] recently appointed to the command of the 1st London General Territorial Hospital.

CITY OF LONDON NURSING SERVICE.

At a meeting of the executive committee of the Territorial Nursing Service of the City and County of London, held at the Mansion House on April 30th, Colonel Clement Godson, Colonel Adams, and Colonel Thorne were added to the executive committee.

LECTURES ON ARMY SANITATION.

The following course of lectures on army sanitation have been arranged and will be delivered at the Royal Institute of Public Health, 37, Russell-square, London, W.C., as follows: May 12th, The Officer and his Duties towards the Well-being of the Soldier under his Command, by Surgeon-General G. J. H. Evatt, C.B., Honorary Colonel, Home Counties Division, Field Ambulances, Territorial Force; May 19th, Practical Sanitation of Camps, by Lieutenant-Colonel R. H. Firth, R.A.M.C., instructor, School of Army Sanitation, Aldershot; May 26th, The Essential Principles of Sanitation in the Field, by Lieutenant-Colonel C. H. Melville, R.A.M.C., professor of hygiene, Royal Army Medical College; June 2nd, Hospital Work in War, by Lieutenant-Colonel R. J. S. Simpson, R.A.M.C., C.M.G., professor of tropical medicine, Royal Army Medical College; June 9th, The Bacteriology of Diseases Common to Armies in the Field, by Dr. R. Tanner Hewlett, professor of general pathology and bacteriology in King's College, London; June 16th, Inoculation Methods for the Prevention of the Diseases to which the Soldier is Liable, by Lieutenant-Colonel S. Monckton Copeman, divisional sanitary officer, 1st London Division, Territorial Force. The lecture hour will be 6 P.M.

MIDDLESEX HOSPITAL.—The annual Middlesex Hospital Founders' Day Commemoration Service will be held in the Hospital Chapel on Wednesday, May 19th, at 3.30 P.M., when a sermon will be preached by the Rev. Herbert E. Gunson, M.A., the chaplain. After the service visitors will have the opportunity of inspecting the wards of the hospital and will be entertained at tea by the invitation of Lord Cheylesmore and members of the weekly board of governors, in whose name the cards of invitation are issued.

Correspondence.

"Audi alteram partem."

THE MEDICAL TREATMENT OF LONDON SCHOOL CHILDREN: THE LONDON COUNTY COUNCIL AND THE CLAIMS OF THE MEDICAL PROFESSION.

To the Editor of THE LANCET.

SIR,—The action of the London County Council demands instant attention and decisive action, if the profession in London is not to be exploited still more, and in a way peculiarly detrimental to its general interests. The Council at its last meeting passed an amendment moved by Mr. Hayes Fisher,[1] referring back a report on the treatment of *school children, with instructions to prepare an estimate of* the cost of treating each of several diseases. The matter is thus left as follows: The Council has decided to treat the children by utilising existing institutions, and by making grants in return from the public funds. The latter, by the way, is in direct opposition to the almost unanimous opinion of the British Medical Association. Following on the passage of this amendment, the authorities, permanent and other of the Education Committee, have approached the chairmen and secretaries of the London hospitals with proposals; and an informal meeting has been held at which a definite proposition was made offering the hospitals *4s. 6d.* per head for treatment. The response to this offer has, I understand, been of a varied nature, some agreeing to a definite remuneration per head, and others saying that if the Council subscribes special facilities shall be given.

In no case does it appear that anything has been said to the staff or that they have been considered in the slightest degree. As far as I can ascertain, they are in more or less complete ignorance of the matter. It seems to be taken for granted that the medical staffs will carry out any scheme that may be proposed by the committees and adopted by the boards of management. In fact, it was bluntly stated the other day, "the staffs are the servants of the boards of management, and if the boards say they must treat the children they must do so." Personally, I think it unlikely that the staffs will submit so easily. In other words, many thousands, probably hundreds of thousands, of children are to be treated as far as the medical profession is concerned for nothing.

There is no doubt that these children need treatment, but if they cannot afford to pay their own private practitioners they should either be treated by the Poor-law or by means of special clinics officered by the medical staff of the Education Committee, who, no doubt, are able and willing to carry out the work in return for adequate remuneration. Can there be a more flagrant example of exploitation than this proposal to utilise the services of the profession without payment to keep down the rates?

I am, Sir, yours faithfully,

London, W., May 1st, 1909. H. BECKETT-OVERY.

⁂ In another column we discuss the situation in the light of a statement circulated among members of the London County Council.—ED. L.

THE PROXIMATE FACTOR OF DELIRIUM TREMENS.

To the Editor of THE LANCET.

SIR,—Referring to Mr. F. S. D. Hogg's letter under this head in THE LANCET of May 1st, p. 1276, I submit that the figures which he extracts from the case-books of Dalrymple Home Retreat are not comparable with those published in the report of the Norwood Sanatorium. Mr. Hogg's figures refer to delirium tremens occurring in the previous life histories of patients, mine to delirium tremens occurring only on or after admission. Moreover, Mr. Hogg's argument assumes that the type of inebriety—whether continuous or intermittent—remains constant through life. If this is the rule there are numerous exceptions. Nothing is commoner than for a continuous drinker to become in the course of time more or less periodic; and conversely. Many of the Norwood Sanatorium patients, periodic drinkers on admission, had suffered from delirium tremens in the past. At the time, however, they had all without exception been continuous drinkers. I have yet to find one instance in which a single short outburst of drunkenness following on a period of total abstinence resulted in delirium tremens.

---

[1] THE LANCET, April 10th, 1909, p 10[illegible].

Both Mr. Hogg and myself now admit that delirium tremens may result from sudden withdrawal of alcohol. But Mr. Hogg finds—contrary to my experience—that the onset of the complication can be prevented by the substitution of other narcotics. In these circumstances exact details of the nature, dosage, and times of administration of the substitutive narcotics would be of great interest and utility.

I am, Sir, yours faithfully,
May 2nd, 1909. FRANCIS HARE.

THE DEATHS REGISTRATION AND BURIALS BILL, 1909.

To the Editor of THE LANCET.

SIR,—It is earnestly to be hoped that this long required measure will be allowed to pass the present session of Parliament and that the medical profession will do all it can to secure that end. I have carefully perused the Bill, which I think is excellent, although there are two or three points on which it appears to me to be hardly complete or definite enough, viz.:—

1. In Section 3, in return for the fee to be paid to the medical practitioner, which I heartily approve, he should be required to give a complete and accurate certification of the cause of death, whether that cause be acute or chronic alcoholism, venereal disease, or whatever it may be. At present the certification and statistics of such causes of death as the last mentioned are most incomplete, because medical practitioners do not like to divulge such confidential secrets to the relatives of the deceased; hence the great desirability also of another amendment, viz.:—

2. In Section 11 it should be compulsory that the medical practitioner's certificate of the cause of death should be sent under sealed cover direct to the sub-registrar. There should also be one compulsory form of medical certificate for the purposes of registration, and one only.

3. Burials should take place only in public cemeteries or churchyards; otherwise there is nothing to prevent still-births being secretly buried in private gardens.

I am, Sir, yours faithfully,
EDMUND M. SMITH, M.D. Edin., D.P.H.,
Guildhall, York, May 4th, 1909. Medical Officer of Health.

PERFORATIVE APPENDICITIS IN AN INFANT.

To the Editor of THE LANCET.

SIR,—In THE LANCET of April 17th, p. 1110, Dr. T. Wilson Parry recorded an interesting case of perforative appendicitis in an infant, aged 16 months. As the condition seems to be extremely rare in infants I think it may be worth mentioning that during the last month Mr. Joseph Cunning operated with complete success on a child just 11 months of age who was admitted to this hospital suffering from a similar condition.

I am, Sir, yours faithfully,
A. C. D. FIRTH,
Resident Medical Officer, Victoria Hospital for Children.
May 3rd, 1909.

THE COST OF A MOTOR-CAR.

To the Editor of THE LANCET.

SIR,—The following particulars of the cost of running a motor-car may be of use to many readers who are interested in the subject either as owners or prospective purchasers of cars.

My car, which I drive myself, is a 12-h.p. "Star," late 1907 pattern, with dual ignition, each totally independent of the other, four speeds forward, with direct drive on the third, and White and Poppe carburettor. I can endorse all the remarks made by your contributor, Mr. Hirsch, about the "Star" cars in "Motoring Notes" in your issue of Feb. 20th last. I have had absolutely no trouble with the car and have run 6800 miles during the last 15 months. The first year's cost of upkeep has been as follows:—

	£	*s.*	*d.*
Petrol	18	19	8
Tyres	9	17	1
Minor repairs	3	3	3
Oil, grease, and sundries (including spare plugs, &c.)	2	12	7
Insurance and licence...	14	5	0
	£48	17	7

The mileage for the 12 months was 6045 miles.

The above speaks for itself and is very satisfactory in every way.

I am, Sir, yours faithfully,
Liverpool, April 27th, 1909. J. SAFFLEY, M.B. Edin.

MEDICAL PRACTICE IN PERU.

To the Editor of THE LANCET.

SIR,—In an editorial article in THE LANCET of Jan. 23rd you say, "In Peru also unqualified practice does not appear to be penalised." Quite correct in one way, but it is strictly prohibited, the delegates of the Medical Faculty having power to call in the action of the civil powers to exact fines, and even, I believe, to put in prison in case of contumely.

During about 50 years I have never seen the law really put in practice in a serious manner, consequently unqualified practice and mendacious "medical" advertisements abound.

I am, Sir, yours faithfully,
J. DICKSON HUNTER, M.D. Edin., &c.
Arequipa, Peru, April 2nd, 1909.

FAVUS AND RINGWORM AMONG SCHOOL CHILDREN.

To the Editor of THE LANCET.

SIR,—In the report on the medical treatment of school children presented at the last meeting of the London County Council the Council's Education Committee recommend the x ray treatment for ringworm, and further that the "present special treatment" of cases of favus should be continued. It is stated that the loss in grants through ringworm amounts to over £5000 per annum, in view of which fact it is obvious that special steps are necessary with a view to the reduction of the excessive prevalence of the disease. At the same time it is pointed out that the x ray treatment costs from 5*s.* to 7*s.* per head, and each installation of the apparatus about £100. The treatment given in the favus school is regarded as satisfactory, and this being so it would be interesting to know why that or some similar treatment cannot be given in cases of ringworm.

Perhaps one of your readers could enlighten me through the medium of your columns as to the nature of the treatment at the favus school, and how it compares as regards cost with the proposed x ray treatment.

I am, Sir, yours faithfully,
May 6th, 1909. M.D.

THE IRISH UNIVERSITIES COMMISSIONS.

To the Editor of THE LANCET.

SIR,—In your issue of April 24th, 1909, on p. 1214, under the above heading, it is stated: "The two commissions ...... are working hard, so that if possible both new universities may be able to begin work next October, when, if they are both ready, the Royal University will be dissolved." As a graduate in medicine of the late Queen's and now Royal University I am anxious to emerge from the state of Egyptian darkness in which I am at present as to the effect of the dissolution of the Royal University on the graduates of that body; in what form will they survive this second death? and where may they expect to find authentic (official) information on the subject?

I am, Sir, yours faithfully,
May 1st, 1909. MORIBUND.

⁂ We have the fullest sympathy with our correspondent. We believe when the Royal University *is dissolved* he may enrol himself either as a graduate of the National University of Dublin or of the Queen's University of Belfast, or he may decide to take neither course, but to describe himself officially as M.D. (late R.U.I.). He can obtain official information on the matter by communicating with the Right Hon. Lord Chief Baron Palles, chairman of the National University Commission, Mount Anville House, Dundrum, county Dublin, or with His Honour Judge Shaw, K.C., chairman of the Belfast University Commission, 69, Pembroke-road, Dublin. Each of these gentlemen, with a few others from both commissions, will sit together in Dublin on May 14th to decide questions that affect the two universities, of which the subject raised in the above letter is, we should presume, likely to be one.—ED. L.

THE GERMAN SURGICAL CONGRESS.[1]

(FROM OUR BERLIN CORRESPONDENT.)

THE Congress [illegible] eld at Berlin from [illegible] of Hamburg being in the chair.

Anæsthetics.

Professor NEUBER of Kiel made a report on a collective investigation concerning Anæsthesia during 1908. In all 71,052 cases were registered, in 24 of which, or about 1 in 3000, death occurred. The mortality in anæsthesia by chloroform exceeded that caused by ether; the latter, however, more frequently produced post-operative pneumonia. Chloroform, which in Germany was formerly used in 75 per cent. of the cases, was now used only in 25 per cent. The combination of oxygen with chloroform, administered by the Roth-Draeger apparatus, had not been so successful as, it appeared, the author had hoped. The least harmful method was the combination of scopolamin and morphine combined with the ether drop method. Anæsthesia should be produced rather slowly and should not be so intense as to cause total disappearance of the reflexes, but only be so deep that no pain is felt and that no movements are made. Irritation is thus avoided before and during the operation; moreover, the danger of pneumonia is considerably decreased.

[illegible] fessor Schleich was the [illegible] of novocaine with adrenalin [illegible] could be given to produce [illegible] removal of even the thyroid gland or the larynx. He then described his method of intravenous injections in the limbs which was lately reported in these columns. Concerning spinal analgesia by injection into the spinal canal, he said that failures were rather rare with a careful technique, but that undesirable sequels might occur. After the injection of tropacocaine and adrenalin headache occurred in 6 per cent. of the cases and vomiting in 5 per cent. The metho[illegible] lower [illegible] amin [illegible] in cas[illegible] suffer[illegible] ever, [illegible] an experiment.

Professor REHN of Frankfort had made experiments in animals concerning the influence of lumbar injection on the spine and the brain. To study the physiological current of the arachnoidal fluid 2 cubic centimetres of a sugar solution with methylene blue were injected into the lumbar [illegible] t being that [illegible] 25 minutes [illegible] fore obvious [illegible] the physio- [illegible] novocaine, [illegible] three hours within the [illegible] pounds appea[illegible] that stovaine [illegible] the motor ganglia of the brain chromolytic alterations and degeneration were found 72 hours after the injection. After ten days a degeneration of the cord, especially of the posterior column, was found. The direct injection of the compound into the spinal marrow produced at once a total destruction, whilst injection of a saline solution was harmless.

Professor KADER of Cracow reported 1907 cases of spinal [illegible] e method [illegible] region of [illegible] must be [illegible] cerebro-spinal fluid allowed to escape must be twice that of the solution injected. He injected whilst the patient was in a stooping position, but he was placed in Trendelenburg's posi[illegible] e injection; the quantity injected [illegible] cocaine in operations on the pelvis [illegible] 0·12 gramme in operations above that region, and 0·14 to 0·16 gramme in operations on the neck. As a rule the patients showed no undesirable symptoms, but in four cases death occurred on the operating table. The operations sometimes lasted for hours. In elderly people greater doses must be avoided. In 81 cases general narcosis became necessary. Twice syncope was observed, in five cases severe headache occurred, and in three cases paresis of the ocular muscles followed, which, however, disappeared later.

[illegible] hat the arabates of [illegible] up the spinal canal, [illegible] hlorates; in animals a total analgesia of the body, including the cornea, was obtained without paralysis of the respiration.

Dr. HOHEMANN of Rostock spoke on the treatment of the after-effects of spinal analgesia. The most frequent complication was severe headache, which sometimes was present for many weeks and seemed to defy therapeutic treatment. He made exact estimate of the pressure of the cerebro-spinal fluid in the horizontal position after the method devised by Professor Quincke. When the pressure was too high a certain quantity of the fluid was drawn off; when it was too low a certain quantity of a saline solution was injected, the results being very good.

Staff-Surgeon Dr. KÖHLER of Berlin discussed the possibility of local analgesia in a war. He said that, owing to the uncertain effect of the method and the difficulty of securing asepsis in war, general anæsthesia by inhalation was preferable for operation on the battlefield and in the field hospitals.

Operations on the Ureter.

Professor GARRÉ of Bonn said that the most frequent reason for operation on the ureter was incarcerated calculus which was generally situated either at the upper end of the ureter or near its entrance to the bladder. When the ureter was totally blocked no time should be lost but an operation should be at once performed. An incision was made from the twelfth intercostal space to the anterior superior spine. Through this incision the surgeon must get at the calculus by the retroperitoneal way. The calculus might be felt when the ureter was reached. An incision was then made in the ureter and the calculus gently removed. By introducing a probe it could be ascertained whether other calculi or strictures were present. The incision was then closed by suture. It was unadvisable to insert the ureter in the surrounding tissue because kinks and strictures were liable to occur. Drainage of the ureter was contraindicated. In cases of incarceration of calculi near the entrance of the ureter into the bladder the "sectio alta" should be made. The diagnosis of calculi might be made by radiography or by cystoscopy. A second indication for operation on the ureter was the presence of injuries, especially in gynæcological operations; the diagnosis was as a rule uncertain, but when an injury was certain an immediate operation was advisable. The ureter was made accessible in the retroperitoneal way and the wound was closed by fine silk sutures. When the ureter was completely divided an oblique union of the ends was preferable to a circular suture. A lateral anastomosis might hinder the urine from passing freely and it was thus preferable to make an invagination of the renal into the vesical end. The suture of the ureter was impossible within the true pelvis, implantation being the standard method in such cases. Implantation is further indicated in prolapse, in growths of the bladder, and in ectopia. When an implantation could not be done the following procedures might be considered: (1) removal of the kidney; (2) anastomosis of both ureters; (3) nephrostomy; (4) implantation into the sigmoid; and (5) implantation of an organic tube instead of the ureter. The third indication for operation on the ureter was stricture with consecutive hydronephrosis. In such cases either resection with oblique sutures or invagination must be performed.

---

[1] Our correspondent received valuable assistance in the preparation of this report from the editor of the *Deutsche Medicinische Wochenschrift*, whose courtesy we wish to acknowledge.

Dr. **VOLKER** of Heidelberg read a paper on the Diagnosis of Dilatation of the Renal Pelvis. He proposed to fill the pelvis with a solution of collargol through the ureter and to use radiography. The ureteral catheter must be impregnated with bismuth, so that it gave a shadow on the radiographic plate.

Peritonitis.

Dr. **NOTZEL** of Völklingen read a paper on Operations for Diffuse Peritonitis. He said that the prognosis did not depend on the species of bacteria present. As a rule the bacterium coli was found in peritonitis; streptococci if present did not mean a worse prognosis. It was important for a successful result to remember that the peritoneum, like all the large serous membranes, was able to destroy great masses of cocci. The object of the treatment was to remove the cause of the peritonitis, to get rid of the pus, and to provide for thorough drainage. Therefore every case of diffuse suppurative peritonitis was to be operated on, large incisions being necessary. For removal of the pus Dr. Notzel recommended irrigation, which, moreover, had a tonic action on the heart and the intestine. The Trendelenburg position must be avoided, the pelvis, on the contrary, being lowered. Drainage should be carried out by tubes and the wound closed by sutures to restore the abdominal pressure; the drainage tubes might be changed on the second day and replaced by smaller ones. In cases of paresis of the intestines enterostomy had not given good results; eventually puncture of the intestines by small trocars might be performed.

Dr. **NORDMANN** of Berlin said that the better results now obtained were partly due to the early date at which operations for appendicitis were undertaken. An exact diagnosis was rather difficult. Of 75 cases which occurred during the last year, six were not operated upon and died; of 69 cases operated upon, 23 died. Rigidity of the abdominal wall was not an absolutely sure symptom of peritonitis, for it was found also in enteric fever, meningitis, and Addison's disease. Fæcal fistulæ were less frequent since plugging had been abandoned. Dr. Nordmann argued against the use of sutures, because the fascia might become necrotic and suppuration of the abdominal wall might occur. Multiple incisions were no longer performed. The mortality in cases of paresis of the intestines was 75 per cent. Enterostomy and injection of physostigmine were useless.

Dr. **SPRENGEL** of Brunswick said that he avoided irrigation, the dry method giving better results. He also entered a protest against infusions of saline solution as useless; large doses, according to him, prejudiced the cardiac action. Enterostomy had been abandoned by him.

Dr. **BORCHARD** of Posen said that in cases of diffuse peritonitis after appendicitis he gave, after the removal of the appendix, injections of from 50 to 100 grammes of olive-oil. The results were good.

Dr. **HEILE** of Wiesbaden said that after the incision of the peritoneum he made a puncture of the intestine and injected about 50 or 100 grammes of castor oil to produce peristaltic movements. The small opening was then closed by a suture.

Dr. **ROTTER** of Berlin said that he preferred to close the abdominal wound by sutures in appendicitis with peritonitis. He had only twice observed an abscess in Douglas's pouch after this method. But in general diffuse peritonitis he warned his hearers against sutures.

Dr. **KOTZENBERG** of Hamburg recommended irrigation and injection of a vioform (iodochloroxy-quinoline) emulsion. To produce peristaltic movements he administered strychnine in large doses. He took the opsonic index, which, according to him, was valuable for the diagnosis, but without value in prognosis.

Cancer.

Professor **VON CZERNY** of Heidelberg said that an operation was still the best remedy for cancer, but that in inoperable cancer other methods must be tried; he hoped that eventually when the etiology of cancer was ascertained a serum would be found against the disease. Actually the method of Keating-Hart was one of the best proceedings for the treatment of cancer. Combined with excision and shelling-out it might not only relieve the patient but might eventually bring about a cure. After excision of the growth the wound was "fulgurated" and a scar was produced; and later granulation and epidermis often developed. He also recommended the administration of a radio-active salt obtained from the Kreuznach springs.

Dr. **COHN** of Berlin said that according to his experiences the Keating-Hart method did not destroy cancer but produced a very quick cicatrisation.

Wound of the Pulmonary Vein.

Professor **VON EISELSBERG** of Vienna reported the case of a Stab Wound of the Pulmonary Vein. The vein was made accessible by temporary resection of the third and fourth rib and the wound was closed by six sutures. The operation was completed within ten minutes. The patient, who was conveyed to the hospital in a moribund and pulseless state, recovered immediately; the pulse in the radial artery appeared as soon as the wound was closed and the hæmorrhage stopped. Unfortunately, the patient died after six weeks from empyema, which was probably metastatic, the primary cause being multiple abscesses in the skin due to injections of morphine.

(To be continued.)

THE DRAINAGE OF CAIRO.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

(Concluded from p. 1279.)

The Educational Influence of Good Sanitation.—The Complete Abolition of Cesspools.—A New System of Connecting and Disconnecting the House Drains with the Sewers.—The Mosque Latrines and the Public Latrines.—Religious Teaching and Cleanliness.

Cairo.

HAVING described the general scheme in regard to the public sewers, it is now necessary to consider its bearings upon the population, which amounted, according to the census taken in April, 1907, to 644,000 souls. For sanitary purposes this population has been divided into an upper and a lower class. The former consists of 50,000 Europeans and 50,000 Egyptians. Among the 544,000 belonging to the lower class—and I took care to make particular inquiries in this respect—there are a number of Europeans. It would be a great mistake to conclude that the sanitary difficulties are, and will be, created only by native Egyptians. The latter, for the most part, are taught by their religion to be clean, though they are quite ignorant of the principles of sanitary engineering. But the lower class European has neither religious nor any other education that would lead him to make proper and decent use of any sanitary accommodation afforded. Therefore there are many Europeans, notably Greeks, Italians, and Maltese, who, by reason of their dirty habits and tendency to overcrowd, cannot be qualified otherwise than as belonging to the lower class, judged from the sanitary point of view. The drainage scheme is based not merely on this dual classification, but on the calculation that in the course of the next 25 years the population will increase to 940,000, including an upper class of 160,000. Against this last estimate I would enter an energetic protest as being too pessimistic. Should it prove correct, then one of the best purposes of such a drainage scheme will have miscarried. It will be noticed that in these figures the proportion of the upper and the lower class in the enlarged population is maintained with something approaching to mathematical precision exactly as it now is. But one of the most fruitful effects of a general drainage scheme is its educational influence on the lower sections of the population. "Are your drains in order?" is the inevitable question which, all the world over, the sanitarian, the social reformer, and the Lady Bountiful have on their lips as they penetrate the slums, bringing enlightenment, help, and sympathy to the least fortunate sections of the community. Thus some even of the poorest classes are taught the importance of sanitation, and from the sanitary point of view are raised to a higher class by their knowledge. If to-day one out of every six inhabitants of Cairo may be ranked as belonging to a sanitary upper class, after 25 years of object-lessons given by carrying out the drainage works, the proportion of those who understand to some extent the laws of health will be raised to two—let us hope to even three or four—out of every six inhabitants Of course, as the knowledge of sanitation increases the amount of water employed will increase Fortunately, the whole scheme of drainage is conceived on the basis that the maximum normal supply of sewage in dry weather will not do more than half fill the sewers Therefore the sewers will be able to drain away double the amount of sewage likely to flow into them at present

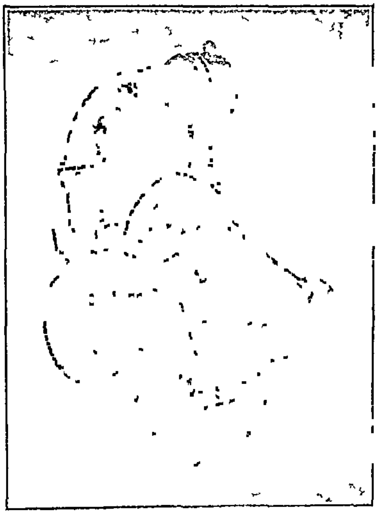
At the same time this question of the amount of water to be carried by the sewers has not been definitely decided, and the present estimate if maintained would constitute the weak side of the scheme I understand that the Cairo Water Company has stated that 18 808,778 cubic metres of water were consumed in 1906, the maximum daily consumption was on June 13th and it amounted to 87,747 cubic metres In winter *only half as much water is used* These *figures* are, however, not of much use as they are based on the existing absence of water closets in most of the houses and on the fact that the majority of the population buy the water they use for domestic purposes Consequently with only the very small quantity of water they can afford to buy domestic cleanliness becomes impracticable Surely the great object of a drainage scheme is, not to perpetuate, but to do away with this state of things The first of all laws of health is to have an ample provision of light air and water The poorer the house the more densely crowded the district, the greater the need of an abundant provision of water so as to replace by constant scrubbing and washing what is wanting in open spaces, light and air In a word, it is the worst quarters, and not the best quarters that need the greatest attention and improvement This obvious fact needs to be emphasised in the plan of dealing with Cairo

The dwellings are divided into three categories There are the houses connected with the actual water distribution and then other good classes of houses that are not so connected Thirdly, we have the houses made of sunburned bricks, *forming* the poorest and most miserable *buildings* The first category of houses have water closets which drain into different sorts of cesspools *fosses* septic tanks, soak aways and other more or less make shift devices All this will be abolished, the receptacles of filth will be carefully filled up and the closets connected directly with the street sewer

The success of these operations will depend on the severity of the supervision exercised The existing cesspools will have to be filled up with clean earth It is no use removing one sort of dirt to replace it with another sort of objectionable matter As it is, everyone knows that the cesspools are a source of danger, and some persons endeavour to cope with this menace by employing septic tanks and other contrivances But when the cesspools are filled up it will be thought that the danger is over, yet it may still be present If the material put in is not suitable or is not itself clean the new state of affairs may be more perilous than the old because it will be unsuspected Having thoroughly cleansed the inside of the houses and removed all trace of the old and barbaric cesspool system the next *thing* will be to establish such connexions with the sewers as will permit the immediate evacuation of all soil and slop water from the houses without letting any air travel back from the sewer into the house *It seems* a paradox but the object is at once to connect and yet to disconnect the houses For more than half a century the greatest ingenuity has been displayed to achieve this double and, as it were, contradictory purpose The method to be employed at Cairo is [illegible] whatsoever about the question Instead of disconnecting chambers, inlet and outlet soil pipe ventilators, a form of interceptor and ventilator shown in Figs 1 and 2 will be placed between the private house drains and the public sewers

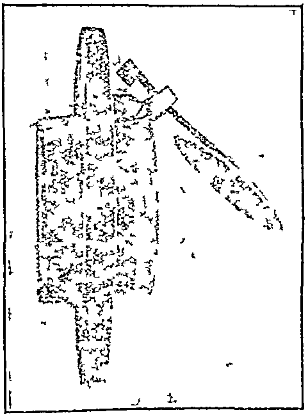
With the assistance of the accompanying illustrations it will be easy to realise the working of this ingenious contrivance The first (see Fig 1) shows the ordinary syphon trap providing a three inch water seal Above this ordinary syphon trap there is a ventilating arm leading to a small circular compartment which holds a carefully balanced valve The valve opens from inside, that is, from the house outward, and is illustrated by Fig 2 If the current of air is from the sewer to the house it closes the valve On the other hand, even a very slight current of air coming from the dwelling, down its soil pipe or its slop and waste water pipes will suffice to raise this valve and thus allow the air to escape into the sewer The current of air passing by the valve must always be from the house to the sewer, while there is the three inch deep water seal as well as the swinging valve to prevent air ascending from the sewer into the house It will be seen at once that the successful working of this apparatus depends on two indispensable conditions First, the disconnecting trap must rest on a sure immoveable foundation

FIG 1



The ventilating interceptor to be placed by the authorities between the private house drains and the public sewers

FIG 2



The valve within the ventilating interceptor which opens to let currents of air pass from the house drains to the sewer but closes to prevent air from the sewer ascending into the house

It has to be evenly poised so that the valve hangs straight down and keeps the aperture closed until the pressure of air from within is strong enough to lift the valve. Like a balance, it must be on a true level. Any negligent workmanship may defeat the whole object of the apparatus. The second indispensable condition is that the syphon trap shall always be full of water. Any scarcity of water might prove fatal to the system, for the seal would fail to prevent the sewer air travelling up into the house. Epidemics are known to have ensued when closets are used which have not been used for a certain time. The water has evaporated from the traps and the sewer air has thus been able to enter the house. This, for instance, occurred at Brussels. Many cases of typhoid fever were noted in the wealthiest and most fashionable part of the town when the inhabitants of luxurious houses returned after the holiday season. During their absence no one had thought of flushing the house drains, the water in the syphons evaporated, and these dwellings were reeking with sewer air by the time their owners returned. The sewers of Brussels are not self-cleansing sewers, so that the danger was much greater than will be the case in Cairo if the ideal of a truly self-cleansing sewer is realised. For that purpose, however, there must be sufficient water. For the houses that are to drain direct into the sewers and are to be protected by the intercepting and ventilating trap I have just described, it is estimated that there will be a supply of water amounting to 150 litres per head per day. This, however, only covers a very small part of the ground, and it is situated for the most part in the European quarter. At present the accommodation in the greater number of the private houses is so filthy and repulsive that a large proportion of the men prefer frequenting the mosques.

Mr. Carkeet James states that he has obtained from the mosques an estimate of the number of people using the mosque latrines and the water they consume. Roughly, about 150,000 daily make use of the mosque latrines, but out of 352 mosques no less than 259 raise water from their own wells, and only 93 subscribe to the water company's supply. Obviously the water from wells dug in such a soil as that of Cairo is only fit to flush closets. The Wakf administrators who control the mosque property have fortunately expressed their desire to help in the realisation of the drainage scheme, and the hope is also entertained that they will do away altogether with these very suspicious wells. In dealing, however, with the statistics relating to the mosques, there is the same hopeless tone against which I have already protested. Thus the estimate is made that in 1932 the number of persons frequenting the mosque latrines will be 215,000 per day; yet surely by that time the accommodation in the dwelling houses will have so improved that, in spite of the increase of population, there should be a decrease in the number of people making use of the mosque latrines. Besides, whatever is done at the mosques only concerns men. From a sanitary point of view women and children represent as important a section of the community, and a larger section.

Then, again, it seems to me that, in the plans and calculations formulated in regard to the public latrines, we have another illustration of a want of that faith in human progress which should constitute the spirit and the strength of sanitary reform. We are left to infer that these public latrines are a public necessity, not for those persons who are too far away to reach their homes, but as a substitute for the accommodation every home should contain. The public latrine is not to be a convenience, but it is to be a means by which it will be possible to postpone the supply of proper closets in private houses. It is proposed to construct about 400 urinals and latrines, having an average of ten seats each. Then there is the astounding statement that, deducting the upper classes and those who use the mosques, there will be in 1932 a population of 565,000 available for using the latrines daily, and they are magnanimously allowed ten litres of water each! If the 400 latrines are to have ten seats each, this makes 4000 closets for 565,000 people, or 140 persons for each closet. Our Common Lodging-houses Act is no grandmotherly specimen of modern legislation. Though it is one of the best among our sanitary laws it was enacted as far back as the year 1851. It does not legislate for the privileged classes nor for the upper classes so carefully parcelled out and set aside in the Cairo sewage scheme. It legislates for the outcast, the vagabond, the tramp, the beggar, the thief, the outlaw; and under the sliding scale of accommodation permitted by the Act the London County Council has declared that none of these social wrecks shall have less than one closet for every 12 inhabitants of a common lodging-house. This is the accommodation which in London is declared necessary for the poorest of the poor. Nor is this a mere affirmation of a principle. Throughout the length and breadth of the country the law is strictly applied on some such principle, and it has proved of the greatest benefit to the poorest and most degraded sections of the community.

Obviously the figures I have quoted are not serious. They represent simply an extreme statement, a calculation made to show that, even if a sufficient amount of water cannot, for the time being, be obtained, Cairo will nevertheless be drained; the cesspool will be abolished, the filth will reach the sewers, the contamination of the subsoil will cease, and an immense progress will be achieved. In every part of the great town the streets will have sewers. Instead of remaining in the town for years, soaking gradually into the subsoil and contaminating the surroundings, sewage, even if it is produced at the farthest extremity of old Cairo, will travel in less than five hours the whole length of the sewers and reach the sewer outfall in the desert, where it will be beyond the possibility of doing any harm. The far-reaching character of such a change is not easily to be appreciated by those who have no practical experience of such matters.

Remains the question of domestic drainage, especially that of the poorer houses and their connexion with the sewers. This is a phase of the problem that has not yet been settled. As it is of the greatest practical importance, it is fortunate that there is no need of immediate haste. The outfall and main sewers have to be built, and then must follow the branch sewers; the connexion with the houses is the last, the final, step. The nature of the house drains will depend first on the amount of water available, and secondly on the possibility of teaching the population how to make proper use of proper water-closets if these are supplied. In the meanwhile, Mr. Carkeet James is determined that there shall be no lack of public latrines, especially for the use of women and children. The plans and the drawings for these are already prepared, and they constitute conclusive circumstantial evidence to prove that the native Egyptian is capable of being taught to observe sanitary rules. Each closet will be provided with a tap on the right hand side, so that, according to the sacred law, water may be taken in the right hand while the left hand holds the clothes and helps to wash. Not only does the Mohammedan wash before prayers but after frequenting the latrines. Cheap paper being a European and comparatively modern contrivance, most Egyptians carry round, smooth stones in their pockets. These are of two sizes, the smaller ones being used carefully to remove and throw away with the stone the very last drop of urine. Such minute care is quite unknown among Europeans. But is it not obvious that if all these people can be taught to collect and carry about these stones for such purposes, and constantly to wash themselves according to a well-established ritual, they could with equal, with greater, facility be taught to pull a string so as to flush the pans and syphons of proper water-closets should these be provided? Indeed, when some years ago a public and paying latrine was opened in the Ezbekiyeh Gardens the first person to patronise this establishment was a Greek. He, however, made a great disturbance when asked for the small sum charged, and not only left without paying, but it was subsequently discovered that he had purloined a towel and a piece of soap. The Egyptian is far more docile and easy to govern. Apparently, however, no effort is to be made to introduce the use of paper, for the plan of the public latrines provides catch-pits to collect the stones and prevent their reaching the sewers.

The details for the drainage of the dwellings of the poor have not yet been settled. Experiments will be made; there is no need of at once settling on a uniform plan. But it has, in any case, been decided to do away with the horrible and leaking cesspools which exist in many of these wretched houses. Further, a contrivance has been suggested which might be employed temporarily and until such time as proper closets can be introduced. It would prevent the contamination of the subsoil. The great fact is that sewers are about to be built; that there is every reason to believe that they will work well, promptly and safely removing the sewage which is emptied into them. How far the houses by the side of the sewers will avail themselves in a thoroughly satisfactory manner of the facilities thus offered depends, I repeat, on the provision of sufficient water and on the intelligent understanding by the inhabitants of the purport of drainage. The British people were just as ignorant as the Egyptians, and far less docile and easy to teach. Nevertheless, though there are still dirty and careless people in England who degrade and destroy the sanitary accommodation provided for them, the construction of sanitary closets has, on the whole, worked well and largely contributed to the notable reduction in the death-rate. There is no reason why, with the exercise of tact and by careful teaching, that which has been done in England should not be likewise achieved in Egypt.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

The University of Bristol.

AT a recent meeting of the Bristol city council it was decided, with hardly any opposition, to support the University by a rate of 1*d.* in the £. This will mean an addition to the University income of £7000 per annum; £4000 will go to meet ordinary expenditure, while £3000 are to be reserved for special purposes, particularly scholarships and exhibitions. By the recently published will of the late Sir Frederick Wills the University funds are to receive £5000. The scheme for the establishment of a hostel for women students has now gone so far that arrangements are being made to open a hall of residence in time for the coming session. It is hoped to begin in commodious premises, with a large sunny garden, situated in a high and healthy part of Clifton. The hall will provide separate study-bedrooms, common rooms, library, and all the essential requirements possessed by the women's colleges at Oxford and Cambridge.

The Bristol Royal Hospital for Sick Children and Women.

The annual meeting of the "Ladies' Auxiliary" of this institution was held on April 27th. The report showed that during 1908 34,620 houses had been canvassed by ladies and the record sum of £823 collected.

Sanitary Inspectors' Association.

The quarterly meeting of the south-western centre of the Sanitary Inspectors' Association was held at the Guildhall, Bath, on May 1st. The delegates were received by the Mayor of the city. Mr. Moss-Flower opened a discussion on "The Need or Otherwise of the Intercepting Trap in House Drainage." Subsequently the old Roman baths and the modern bathing establishment were inspected by the visitors, who were entertained by the Mayor.

Death Certification by a Midwife.

An inquest was held at Crowlas, Cornwall, on April 26th, relative to the death of the twin children of a local miner. Evidence showed that the mother of the children was attended in her confinement by a registered midwife and that one child died two days after birth and the other lived some five days later. The midwife gave a certificate that the children had died owing to premature birth, and the grave-digger of Crowlas Cemetery buried the children on the "authority" of this certificate. Eventually the coroner ordered the exhumation of the bodies and a post-mortem examination. The medical evidence showed that death was due in both cases to congenital inanition. The coroner (Mr. . Boase) said that the midwife had behaved in an extraordinary manner and he should report her to the county committee as being unfit to be entrusted with a certificate, and he should draw the attention of the local authorities to the necessity of framing regulations for the management of the cemetery, as the grave-digger had stated in his evidence that "he considered he could bury six weeks' old children, which he termed stillborn, upon the certificate of a nurse." The jury returned a verdict in accordance with the medical evidence and added riders endorsing the views of the coroner.

The Taunton "Association to Aid Consumptives."

The annual meeting of the friends of the "Taunton Association to Aid Consumptives" was held recently, under the presidency of Mr. H. T. Rutherfoord. The report stated that nine patients had been admitted to the sanatorium during the past year and ten patients had been discharged. The financial statement was satisfactory and showed a favourable balance.

National Poor-law Officers' Association.

The Devon and Cornwall Branch of the National Poor-law Officers' Association held its quarterly meeting at Bodmin on April 24th, [illegible] ing address [illegible] Commission. [illegible] the members was that the suggested change in Poor-law administration was not desirable.

The Exeter City Asylum.

At a meeting of the Exeter city council held on April 28th the resolution which was passed at a previous meeting to enlarge the City Asylum at a cost of £10,000 was rescinded by 27 votes to 22.

The Royal Mineral Water Hospital, Bath.

The annual meeting of the governors of the Royal Mineral Water Hospital, Bath, was held on May 1st under the presidency of Colonel M. Ricketts. The report stated that as the year closed on Dec. 31st last instead of in March as heretofore, the period under review was therefore only nine months. During that time the daily average number of in-patients was 144, compared with 147 in 1907–08. There had been a slight increase in annual subscriptions and donations but a deficit balance of £1018 remained. The committee regretfully records the death of Dr. Charles Coates who had been connected with the hospital for so many years.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

A Deficiency in Medical Inspection Reports.

MEDICAL inspection reports from various surrounding towns and districts continue to appear and are published in a more or less abbreviated form. All the published reports show a certain average of bodily and mental defects which might have been thought to be easily recognisable without the expensive machinery now at work, yet none give any satisfactory account of the relation of defects to the bodily physique, though occasionally, as in Dr. W. C. Garman's recent report for Wednesbury, a statement appears that the children are below the normal standard and the average height and weight is given. No general attempt has yet been made to show any correlation between the unsatisfactory physique and the actual bodily deficiencies, and still less has there been any attempt to estimate the relationship of the physique of the children to that of the parents and to the staple employments of the district. At present, it would seem, a large State organisation is engaged in performing the duties of the parents, for any ordinarily thoughtful and careful parents, considerate of and desirous for the welfare of their children, would readily recognise the majority of the disabilities mentioned in the published records of medical inspection, and would have them attended to either by their own medical adviser or at one of the numerous medical charities. If their natural inclinations do not induce them to exercise proper parental care, parents should be stimulated to their duties by the imposition of penalties for neglect rather than encouraged to neglect them and transmit them to a State organisation, and they might also be called upon to report to the proper authorities any physical or mental disabilities likely to interfere with education. If this were done then the scientific skill at present largely occupied in mere recording could be utilised to investigate the relationship between the physical condition of the children and their environment and heredity, an investigation which promises much more useful information to the State than that which is published in this neighbourhood as the results of medical inspection.

The Women's Hospital.

Three very satisfactory features are noticeable in the annual report of the Women's Hospital. They are the reduction of the death-rate to 0·77 per cent., a diminished expenditure, and an increasing income. The total number of new and old patients treated was 18,845, or almost 1200 less than in the previous year. The number of new out-patients was 3573, being 181 more than in 1907. 742 in-patients were admitted, a decrease of 37 as contrasted with the previous year, and there were 719 operations, of which 385 involved abdominal section. The decrease in the expenses is perhaps to be attributed to more careful supervision of detail. The increase of income is due very largely to the efforts of the recently formed Women's Hospital League, which has collected subscriptions of £57 and donations of £478, and in part to the fact that it has been possible to invest some of the legacies. In spite, however, of the improvement of the finances the excess of expenditure over income was £1020. Therefore work still remains which will test the ability of the Women's Hospital League.

The Birmingham Infants' Health Society

The report presented at the first annual meeting of the Birmingham Infants' Health Society contained not only a record of good work accomplished but also a promise of still better results in the future. So far the work has been limited to one of the worst districts in the city, St. Bartholomew's ward, which contains a population of 22,759 in a space of 313 acres. It is therefore a crowded population and its infantile mortality is 201 per 1000, a figure which clearly indicates deplorable conditions. After the society was formed an infants' consultation was started and in connexion with this 204 children were registered, of whom 190 were under 12 months old. 43 of the 190 were lost sight of, leaving 147; of these, 14 died, giving an infantile mortality-rate of 95·2, which contrasts very favourably with the general rate for the whole ward. Naturally, for several reasons, too much stress cannot be laid upon this figure at present, but it is a hopeful sign, and its significance is increased by the fact that not only was improvement noted in the children but also in the cleanliness of their mothers.

Two Health Reports, Mid-Warwickshire and Smethwick.

The record of falling birth-rates has become so monotonous and regular that one is inclined to accept as inevitable Dr. G. Wilson's report of a slight but still further fall in Mid-Warwickshire from 23·7 to 23·3 per 1000 for the total population, the variations being from 29 in the Southam rural district to 19·4 in the Warwick rural district. On the other hand, Mr. W. F. Marsh Jackson's report of a slight but distinct increase in the Smethwick district is very pleasantly surprising, and Smethwick's birth-rate of 30 per 1000 compares very favourably with the general rate for England and Wales, which is 26·5 per 1000. When the infantile death-rates are contrasted, however, Smethwick's position is not so favourable, the death-rate for Mid-Warwickshire being 88 per 1000 for the combined districts, as compared with 110 per 1000 as the average for rural and small urban districts in England and Wales, whilst Smethwick's rate is 135 per 1000, which does not compare well with the well-populated district of Yardley in the Mid-Warwick area, where the infantile death-rate was only 100 per 1000. Clearly there is room for the work of an infants' health society in Smethwick.

The Diagnosis of Syphilis of the Nervous System.

At the last meeting of the pathological and clinical section of the Birmingham branch of the British Medical Association Dr. F. W. Mott opened a discussion on the diagnosis of syphilis of the nervous system with a brilliant and lucid paper which embodied the results of his own long experience and extensive researches. He emphasised the extreme importance from the point of view of treatment of an early differential diagnosis between syphilitic, pseudo-syphilitic, and parasyphilitic conditions. He laid great stress upon the ruder and coarser results produced in the earlier stages as contrasted with the more insidious and persistently progressive effects of the disease in its later periods, and he expressed the opinion that whilst great reliance could be placed upon the curative action of a proper course of mercury in the earlier stages that drug was little use, if not even harmful, in the later stages. It was generally admitted that the differential diagnosis was in many cases extremely difficult, but it could be made practically certain by careful examination of the cerebro-spinal fluid and the use of the Wassermann reaction. Unfortunately the Wassermann test is not one that can be applied in ordinary practice nor even in hospital wards, and at present it cannot even be made in many otherwise well-equipped pathological departments; it is hoped, however, that before long it will be possible to apply the test in the University pathological laboratory.

(From our own Correspondent.)

Dr. E. W. Hope's Silver Jubilee of Office: Interesting Presentation.

A pleasant gathering was held on April 30th at the Municipal Offices, over 170 members of the sanitary staff of the corporation assembling to do honour to the medical officer of health (Dr. E. W. Hope) who recently completed 25 years of civil service. Dr. A. A. Mussen (assistant medical officer of health) presided over the enthusiastic gathering, which included all the lady sanitary inspectors, each of whom carried a few flowers and so lent a festive aspect to the proceedings. The chairman, before presenting Dr. Hope with an illuminated address and an antique silver tankard, spoke of his distinguished services and the zeal which he had shown for the highest interests of his staff. Not only were Dr. Hope's annual reports among the best of their kind, and thus nationally recognised, so that his position as an authority on public health was very high, but his evidence on sanitary matters was sought in the law courts and before Royal commissions and departmental committees, while he was often consulted by Government officials. All the members of Dr. Hope's staff trusted it would be long before he qualified under the retirement scheme, and personally he (Dr. Mussen) thought this celebration of 25 years' service was a splendid idea. The prestige of the staff was now at its highest, and Dr. Hope was a chief who always gave credit to those who worked well for him. He wished Dr. Hope might be spared for another 25 years. Other officials heartily endorsed Dr. Mussen's remarks. Dr. Hope, in accepting the presentation, said it was difficult to realise that he was in his twenty-sixth year of service while seeing present faces which had been around him all those years and which were so little changed. The most important duty of his early days as medical officer of health was to certify patients suffering from typhus fever. Within the first six months he certified more than 1000 such patients, but to-day typhus fever was looked upon as a rare disease and as pointing to something which ought not to exist. The city had 25 years ago no municipal hospital and he had to depend on the good offices of the boards of guardians, which rendered the city admirable service then and had done so ever since. Even when a city infectious hospital was opened in Grafton-street it was sometimes so difficult to induce a patient to go there that a magistrate's order had to be obtained, and the patient compelled by force to enter the hospital. Nowadays, if the patient was not promptly taken to hospital the relatives and friends quickly wanted to know the reason why. 25 years ago there was no system of notification of infectious disease. His staff was then small, only about a dozen. Since then, however, a series of Acts of Parliament, some being originated by the Liverpool corporation, had been put into operation, with a consequent increase of the health office staff, while the central growth and extension of the city from 450,000 inhabitants to over 750,000 had been accompanied by an automatic multiplication of inspectors. The sanitary work of the port, through which as many as 400,000 emigrants passed in a single year, and the enormous importation of foodstuffs, had led to enlarged work for inspectors, while the task of caring for the health of the children in the schools was only just beginning, and the notification of births would lead to still more duties being cast on the health office. What was there to show for all this sanitary zeal? Well, unhealthful conditions had been swept away which if present to-day would shock the public eye, so that on the negative side there was much to be credited to sanitation which was invisible. There was, however, one great fact to be proud of and to be seen—the remarkably improved health of Liverpool. That was the reason of the existence of his office—the improvement of the public health. It was by one continuous, united, concerted effort that improvement in the health of the city had been effected. The improvement had taken place, not only in the old parish and Parliamentary borough of Liverpool, but in all the districts which had been absorbed in the municipal area. One great argument against the absorption in 1895 was that the health of the out-townships was so good that it could not be improved. Improvement, however, as great as that in the old parts of the city had been since wrought in the suburbs. The Town Planning Act, which by the provision of wide streets and open spaces was to prevent a repetition of the errors of the past, would result in a further great development of sanitation. Moreover, people were increasingly willing to listen to advice concerning their health and that of their homes, and he was glad to say the poor people were as amenable and as willing and anxious to do what they could for themselves in a sanitary sense as any other class. In short, sanitary science had reached a stage at which the city and the nation would advance at an accelerated rate. He would always prize the beautiful gifts he had received.

The Sleeping Sickness Expedition of the Liverpool School of Tropical Medicine.

At the last meeting of the African trade section of the Liverpool Chamber of Commerce Dr. Allan Kinghorn, a member of the sleeping sickness expedition, gave an address upon the investigation of sleeping sickness. He pointed out that the tsetse fly had a wide distribution over the whole of the territory with which the expedition had been dealing, and cattle diseases due to varieties of trypanosomes, and referable finally to the agency of this fly, were abundant everywhere. The absolute safety to life ensured by European administration, the opening of markets for the sale of local produce, and the demand for a constant and abundant supply of labour had resulted in an unprecedented movement amongst the native population; and, as until recently no checks had been imposed on this, many new foci of sleeping sickness had been established, for which we were now paying the price. Most Governments were taking action, but the harm was done before the cause and method of spread of the disease were known. It was formerly thought that only the negro race was affected. The comparative safety of the white man was due to his clothes and the other conditions under which he lived. Wherever the glossina palpalis existed in the presence of an infected person there existed the danger of the spread of human trypanosomiasis. Whilst this species of fly, known as the river fly, was capable of transmitting the disease, some doubt existed as to whether it was that fly only which could do so. He considered it safer to hold the view that other species of tsetse fly might transmit it also. In order to check the spread of the disease the indiscriminate movement of the native population must be controlled. The glossina palpalis required shade and could be got rid of by making clearances along water courses which must be thorough. International coöperation was necessary in dealing with sleeping sickness.

(FROM OUR OWN CORRESPONDENT.)

The Appointment to the Department of Pathology in the Royal Infirmary and College of Medicine.

IN a former letter I drew attention to the fact that the house committee of the Royal Victoria Infirmary had come to the conclusion that the time had arrived when the work of the pathological department should be in the hands of a skilled pathologist devoting his whole time to that branch of medicine. Feeling, very properly, that it was desirable, if it could be arranged, that the infirmary should associate itself with the College of Medicine in taking this step a conference was arranged between the two institutions to discuss and if possible to come to some mutual arrangement whereby they should make a joint appointment. The outcome of the conference was the appointment of a joint committee to advertise for and select a candidate for the position of pathologist to the infirmary and lecturer on pathology at the College of Medicine. In response to its advertisement the committee received applications from a number of suitable candidates, and after duly considering these it recommended that Dr. Stuart McDonald, M.D., F.R.C.P. Edin., be appointed. This recommendation was approved by the house committee and by the College, and Dr. McDonald has therefore been appointed. Dr. McDonald is at present lecturer on pathology and bacteriology in the School of Medicine of the Royal Colleges, and School of Medicine for Women in Edinburgh, pathologist to the Royal Hospital for Sick Children and to Chalmers' Hospital, Edinburgh, and examiner in pathology for the Conjoint Board for Scotland. The committee is to [illegible] ...ate and Dr. [illegible] l important [illegible]

The Newcastle Sanitary Committee's Estimates.

The Newcastle city council has reduced the estimates presented by the sanitary committee for the ensuing year by £3000. The corporation decided that, in view of the present state of trade depression—which in the opinion of those most competent to judge, shows no signs of immediate improvement—it was desirable that there should be no increase in the rates. The various committees were therefore instructed to exercise the most rigid economy in preparing their estimates, and though this was presumably done the sanitary committee has had its estimates altered as stated above. In view of this restriction upon its expenditure the sanitary committee has notified four of its health visitors that it can no longer retain their services. This is a very serious matter for the four women, who thus lose their appointments through no fault of their own, and they are deserving of every sympathy in their present unfortunate position. This decision of the sanitary committee raises an important question of principle, for if the precedent thus set up of dispensing with officials during an outburst of economy be followed it naturally results that capable persons will be very chary of accepting positions under a corporation which is likely to discharge them for no better reason than that it is unwilling to ask for the money wherewith to pay their salaries.

Death of Dr. James Limont.

It is with much regret that I have to record the death of Dr. James Limont, which took place in Edinburgh on May 1st, after a lingering illness which lasted some two and a half years. Dr. Limont was a son of the Rev. W. Limont, a Presbyterian minister, and was born at Alnwick on April 9th, 1856. He was educated at Alnwick Grammar School and subsequently at Edinburgh University, where he graduated M.A. with honours in 1878, B.Sc. in 1879, and M.B., C.M. in 1880. In 1882 he became a Member of the Royal College of Surgeons of England and was admitted a Member of the Royal College of Physicians of London in 1886. After qualifying in medicine Dr. Limont was appointed house surgeon to the Edinburgh Royal Maternity Hospital and the Simpson Memorial Hospital, and also became senior demonstrator of anatomy in the Minto House School of Medicine, Edinburgh. From Edinburgh Dr. Limont went to Glasgow to undertake the duties of house surgeon and house physician to the Glasgow Royal Infirmary, and it was during this time that he came under the influence of Mr. (now Sir William) Macewen. It is about five and twenty years ago that Dr. Limont came to Newcastle on being appointed senior house surgeon and house physician to the Royal Infirmary. In 1885 he was elected an honorary physician to the infirmary and was reappointed to that position in 1900. Dr. Limont devoted himself especially to the study of diseases of the skin and was appointed a physician in charge of the skin department at the infirmary some 14 years ago, and it is to his skill and unfailing interest in the work, ably assisted as he was during the last 11 years of his tenure of the appointment by Dr. D. Wells Patterson, that the department owes its present efficiency and importance. Dr. Limont was joint lecturer in clinical medicine and had been an examiner in medicine in the University of Durham. In the College of Medicine Dr. Limont held the lectureship in medical jurisprudence. Dr. Limont was a man somewhat reserved in manner, but to those who enjoyed his confidence he was of a genial disposition and a very true friend. His death will be a great loss to the teaching staffs of the infirmary and the College. Dr. Limont leaves a widow, one son, and four daughters.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Observations on Growth.

AT a recent meeting of the Royal Philosophical Society of Glasgow a paper was read by Dr. Arnold H. Gray on the Laws of Individual Growth. Dr. Gray began by stating that he had obtained a long series of records of the rate of growth of boys from one of the public schools, and that he had made a series of observations on the mode of growth in animals and plants. The work had been undertaken because, although there was a large amount of information on average growth, at present very little existed concerning the different methods of individual growth. From the series of school observations where the heights and weights were taken at frequent intervals it was found that the rate of growth might be regular, irregular, or cyclic. In the regular type the child increased at a uniform rate. This type was not common in the human subject, occurring in only 12·3 per cent. It was also rare in the case of rabbits and guinea-pigs, but was the usual mode of growth in the internodes of plants. The irregular type was the common form in man, and found to the extent of 83 per cent. Growth was interrupted for periods of indefinite length, when the increase was slow or completely suspended, this stage being followed by another, when growth perhaps was very rapid. This was also the usual type found in rabbits and guinea-pigs. In the cyclic type variations in the rate of increase occurred in a definite order, forming a succession of waves in the curve of growth. It was very rare in man, being observed in only 4·7 per cent. of the cases. It was only occasionally seen in rabbits, though it was representative of the mode of many of the lower animals. In Belvidere Fever Hospital 1395 children suffering from infectious diseases had been weighed and measured on admission and dismissal. The average rates of growth in scarlet fever, measles, and diphtheria were slower than the average rate of growth of children at the same age. In normal children spurts of very rapid growth occurred, and in children suffering from fevers only 65 out of 1395, or 4·6 per cent., showed extreme activity of increase. According to Dr. Gray, temperature, nutrition, and conditions of housing, though affecting growth in general, did not influence the type of growth. The child was born with a tendency, possibly hereditary, towards one form of growth or another, and external agencies played little, if any, part in determining regularity, irregularity, or cyclic variations in the rate of increase.

Consumption in Lewis.

Dr. D. Murray, medical officer of health of the parish of Stornoway, has issued his annual report. He states that through lack of funds, as far as the general sanitary conditions are concerned, the problem remains untouched, although during the year there has been some little improvement on village water-supplies by sinking new and protecting existing wells. To meet the sanitary situation of the island, Dr. Murray suggests as the minimum requirements: (1) education of the people in sanitary matters; (2) practical instruction in hygiene of the school children; (3) an improved type of dwelling-house; (4) loans for building houses and the removals of cottars from congested crofts to "skinned" land; (5) water, drainage, and scavengering schemes; and (6) the rural policemen to act as sanitary inspectors. Anent the last suggestion, Dr. Murray remarks that all acquainted with the social condition of Lewis know that outside the burgh of Stornoway the policemen have practically nothing to do but walk their beats; and he expresses the hope that the red-tape officialism, which divides the public services into water-tight compartments having no connexion with each other, will not be allowed to stand in the way of the police acting as local sanitary inspectors, and doing, as with some training they could, splendid work in the interests of sanitation and public health. Regarding consumption, the statistics are startling. The report states that in the landward part of the parish of Stornoway last year there were 25 deaths from phthisis, and four others from other forms of tuberculous infection. Within the burgh there were nine deaths from consumption, a total of 34 for the whole parish. "If these deaths," the report proceeds, "resulted from fever, the community would be panic-stricken, and ready to make any sacrifice to arrest the plague. While phthisis is too insidious in its operations to have such a dramatic effect, it is an immensely greater menace to the life and well-being of the young people of Lewis than even fever was in its worst days." Dr. Murray is preparing a special report on consumption to emphasise matters, and to suggest lines of action, discussion of which may lead to something being done to arrest the progress of the disease.

University of Aberdeen: Summer Session.

The summer session at the University of Aberdeen commenced on April 27th. The attendance at most of the classes was quite up to the average of former years.

Aberdeen Water-supply: A Serious Pollution.

The water committee of the Aberdeen town council paid a visit recently to the irrigation works at Tarland and Lumphanan, where it was reported contamination of the city's water-supply was taking place. At Tarland the committee found that the tenants who had obtained possession of the ground from the district committee had diverted the sewage from the irrigation field and that it was discharging direct into the stream which joins the Dee at Aboyne. At Lumphanan an even worse state of affairs was found, the ground being absolutely sodden and no irrigation taking place. At both places it was evident that this dangerous condition of affairs had been going on for some time. The committee resolved at once to draw the attention of the district committee to the matter.

May 4th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Second Congress of Physico-therapeutics.

THIS congress was opened on April 13th under the presidency of the Dean of the Paris Faculty of Medicine, Professor Landouzy, who inaugurated the proceedings with an address, pointing out the importance of physical methods of treatment and the necessity for basing their use upon the results of a daily clinical examination. The subject first on the list for discussion was Physical Agents in the Treatment and Diagnosis of Infantile Paralysis. M. Gunsberg of Antwerp, who spoke first, gave an account of the rôle played by mechano-therapy. M. Hirschberg of Paris said that massage, properly speaking, did not cure the paralysis due to the poliomyelitis but was a very useful agent in overcoming the muscular atrophy. Its action ought to be enhanced by motor re-education and gymnastics. M. Libotte of Brussels said that in the acute stage of the disease hydrotherapy seemed to be the only method capable of reducing the inflammation of the spinal cord. Once, however, the paralysis was established this method of treatment could only be considered as an adjuvant to other methods. M. Kouinjy of Paris spoke on the importance of re-education and gave an account of its technique and the indications for it. M. Marques of Montpellier discussed electricity both for diagnosis and treatment. The second question down for discussion was—Physical Agents in the Treatment of Acne and Acneiform Lesions. M. Dausset of Paris, in opening the discussion, said that he did not consider that Bier's method played a very important part in the treatment. For his own part he considered that hot air was useful in the form of a douche as an adjuvant to massage; the suction glass was efficacious, but its employment was difficult and patients disliked it. M. Gaston of Paris said that radio-therapy was the logical method of treatment, for it had a distinct physical and chemical action on glands and might even cause them to atrophy. M. Viel of Paris discussed the question from the dietetic point of view. Every patient must be dieted in accordance with his or her special individuality. M. Oudon of Paris held that the static or else the high-frequency discharge diminished and finally caused the disappearance of the seborrhœa and even of the comedones. It was thus an excellent preventive of further manifestations of acne and enabled the physician to empty and to cleanse the pustules of acute acne. M. Dubois of Saujon discussed the utility of the vapour douche. Various speakers next discussed the clinical and scientific objections to the use of physical agents in the treatment of disease by non-medical persons. All were of opinion that such a custom was highly dangerous. Varix and varicose ulcers were the next pathological conditions to be dealt with. M. Gaston Bloch said that massage was very soothing in painful varices but should be combined with gymnastics and gentle walking. M. Vermeulen dealt with mechano-therapy, and M. Bourcard devoted his speech to massage in phlebitis. He immobilises the limb but gives abdominal massage, which, according to him, reduces the temperature and modifies the composition of the blood. M. Durey discussed hyperæmia in the treatment of varicose ulcers. M. Dubois advised local cold douches for non-complicated varices and hot douches in the case of those which were painful. M. Laquerrière mentioned other local treatments besides those which had for their object the modification of the nutrition and the circulation, and M. Bordet spoke upon the state of the muscles in the case of varicose limbs. Many other papers on various subjects were read at what proved to be an interesting an instructive congress.

Cocaine Anæsthesia for Dislocations.

At a meeting of the Surgical Society held on April 21st M. Quénu gave an account of this method. In a case of backward dislocation of the elbow he injected three centigrammes—i.e., just under half a grain—of cocaine into the triceps, and reduction was easily effected without pain. In another patient a 1 in 200 solution of cocaine was taken and one cubic centimetre was injected in three different places around the elbow-joint. In a dorsal dislocation of the thumb four cubic centimetres of the solution was injected in four different spots around the joint and reduction was painless. In a dislocation of the shoulder injection was made into the deltoid, the pectoralis major, and the latissimus dorsi. The dislocation was of the subcoracoid variety. An assistant abducted the arm and the head of the humerus moved into the axilla, when reduction was easy. Finally, in dislocation of the hip-joint three centigrammes of cocaine were injected at the outer side of the vessels into the cavity of the joint. Reduction was easy. The cocaine besides makes a clinical examination easy, for the spasm of the muscle ceases after injection into the articular cavity.

Treatment of Gangrenous Strangulated Hernia.

At the Forty-seventh Congress of Learned Societies recently held at Rennes from April 5th to April 7th M. Hardouin gave an account of nine cases of this condition on which he had operated. In these nine patients resection of the gangrenous mass was performed in six followed by immediate entero-anastomosis with three recoveries and three deaths. In two cases an artificial anus was made and there were two deaths. In one case the strangulated portion of the intestine was fastened outside, an artificial anus being formed spontaneously afterwards, and death resulted. Intestinal resection in a case of a strangulated gangrenous hernia is the method of election but yet is a very grave operation. In studying the French and foreign statistics of the operation M. Hardouin noted that of 986 cases of resection followed by entero-anastomosis 399 died—viz., a mortality of 40 per cent. In 620 cases of artificial anus there were 447 deaths, or 74 per cent. These statistics date from 1878 and since then the technique of intestinal resection has improved enormously with the progress of asepsis. In recent statistics the mortality of resection of gangrenous intestine has fallen to 33 per cent., and in cases where Murphy's button is used to 8 per cent. Intestinal resection, which is still but little performed in France, seems now destined to take one of the first places in the treatment of such lesions.

The Bacteriological Analysis of Sea-water.

At the same meeting of the same Congress M. Bodin and M. Sacquepee communicated a paper on the bacteriological analysis of sea-water. They had made researches on water taken from the bay of Cancale. This, when collected well out at sea (*au large*), proved to be very pure from the microbial point of view, containing only from 200 to 400 aerobic germs per cubic centimetre. If taken from a depth [illegible] the water taken from [illegible] were met with. Sea-[illegible] purifies itself quickly. Thus water containing 16,500 bacteria per cubic centimetre when taken at the outfall of a sewer contained only 1100 when taken at a distance of 100 metres away and at 400 or 500 metres away its composition was the same as that taken *au large*—namely, it contained between 200 and 400 germs per cubic centimetre.

The Treatment of Furunculosis.

At a meeting of the Academy of Medicine held on April 24th M. Mauté gave the results of a treatment which he had adopted in a case of furunculosis. The patient was injected with an antistaphylococcic vaccine prepared by emulsionising the staphylococci obtained from his own pustules in physiological serum. The emulsion contained 250,000,000 of cocci per cubic centimetre and had been sterilised by repeated heating at 53° C. M. Mauté added that observation of patients treated in this fashion had shown him that the vaccine had an undoubted power in preventing the formation of fresh furuncles.

May 4th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The late Commendatore Bastianelli.

A MAN of light and leading in the hygienic world has been lost to Rome, and, indeed, to Italy, in the Commendatore Giulio Bastianelli, who, as an Italian colleague expresses it, "full of years and honours was gathered up like a ripe sheaf." No professional man was better known in the medical or municipal circles of the Eternal City or more highly esteemed for skill as an expert or for "sense of citizenship." Elected as assessor on the Communal Council, he presided over the department of hygiene, and at once the sanitary conditions, urban and suburban, were subjected to a scrutiny and an amelioration which have made the Rome of the last few decades hardly recognisable in her "change for the better." In 1884, when the "cholera explosion" at Naples numbered nearly 2000 [illegible] Upper [illegible] work, [illegible] ed the subsoil wells of Rome, and not only saved her from an imminent danger but protected her from future visitations. This is but one out of many innovations due to his vigilance and energy—innovations proceeding on lines now skilfully and steadily maintained. His two sons, it may be added, with whom in their great loss the citizens are now sympathising, honourably uphold the paternal name—the elder, Dr. Raffaele Bastianelli, professor of clinical surgery in the Roman school, having already given proof of his ability to perpetuate the traditions of his distinguished predecessors in the chair—Costanzo Mazzoni and Francesco Durante.

The Passing of the Duel.

Italy is now setting herself to a task the initiation of which has been too long delayed—that of abolishing the duel, a "method of barbarism" discredited and disused for more than half a century in the British Isles, but still (strange to say) considered not only right and proper but even "honourable" in a country which prides itself on its abolition of that other form of "capital punishment"—the gallows or the guillotine—by which society protects itself from its worst enemies. His Excellency Signor Orlando, Minister of Grace and Justice, following the lead of Signor Casana, lately Minister of War, and of His Excellency Signor Mirabello, Minister of Marine, is exerting himself in this salutary direction, and it is now but a matter of time—and short at that—when the "mediæval survival" will have gone the way of other practices hardly more unworthy of the twentieth century. [illegible] actively in the [illegible] di Parravicino [illegible] ed by 3500 of [illegible] g him in the action he is about to take in Parliament "contro il duello." Another album, not less numerously and influentially signed by Milanese ladies, with the Contessa Elisa Trivulzio at their head, has been presented to the ex-Minister Casana, and his acknowledgment of the memorial is worth noticing as evidence of the opinion that has long prevailed in military circles against the solution of private quarrels by sabre or pistol. What he calls the "assurda è crudele consuetudine," if discountenanced by the upper classes, will react for good on the lower, where the use of the knife or stiletto is still justified by military or aristocratic precedent. Warfare nowadays by land and sea is far too serious a profession for the quixotic notions of "honour"—often invoked on the idlest pretences—to compromise the lives of men dedicated to their country's service. The personal vanity or susceptibility which, when ruffled, cannot be otherwise placated than by threatening or taking the life of the offender, betrays a weakness, moral as well as intellectual, amounting to disqualification for the strategy that precedes, and the self-command that confronts, the sterner arbitrament of the campaign. With all which reasoning, expressed or implied in Signor Casana's deliverance, Italians are now in full agreement, eager as they are to rid themselves of all relics of that "civilisation" for which they find sufficient condemnation in the comprehensive epithet "mediæval."

May 3rd.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Rare Localisation of Secondary Carcinoma Deposits.

AT a recent meeting of the Medical Society of Vienna Professor H. Schlesinger demonstrated a case of typical neuritis of the inferior dental nerve, owing to a secondary deposit of carcinoma in the lower jaw. The patient, a woman aged 48 years, had had an operation done a year ago for carcinoma of the breast. Now metastatic growths are diffused throughout the body. Some four weeks ago the patient noticed pain in the left lower jaw, and examination now shows complete anæsthesia of the skin of the chin, within a line from the lower angle of the mouth to the margin of the lower jaw. The middle line is the median limit of the anæsthetic area. The lip and the gums are anæsthetic to the same extent. The teeth are not displaced. Similar cases have been observed occasionally, and in four of them Professor Schlesinger was able to confirm the diagnosis of carcinomatous deposits in the lower inferior dental canal by post-mortem examination. This localisation seems to be a typical one, as all cases observed hitherto have been very similar to one another. Three cases have been observed after mammary cancer and one after a prostatic cancer. All the cases showed remarkable identical features as follows. The middle line was always the border of the anæsthetic area, although one would not expect this to be so, owing to the anatomical relations of the nerve. There was always paræsthesia, pain appearing only very late in the course of the disease, although the nerve affected is a purely sensory nerve. There were hardly any motor disturbances in chewing, but morsels of food remained between the jaw and the cheek owing to the absence of sensation in this area.

A Case of Chronic Infantile Polyarthritis.

At the same meeting Dr. Algyogy showed a very rare case of chronic polyarthritis with disturbances of development of the long bones and cervical vertebræ, which had been under observation ever since childhood. The patient, now 20 years old, was affected in her sixth year by an inflammation of all joints except the vertebral joints of the dorsal and lumbar region. There was no fever at that time, but acute pain all over the body. The attacks lasted, with slight interruptions, for three full years. The girl shows an abnormally small degree of bodily development. All long bones, most markedly the bones of the upper extremities, are short but straight. The joints are thickened, the cervical vertebral column is hypoplastic, its motility is diminished, especially for movement backward and towards the right side. Skiagrams show that the inter-vertebral discs are much smaller and thinner than normal, and that there are many exostoses on the ankle joints. The carpal bones are so deformed by exostoses that they cannot be differentiated, and all the bones of the body appear to be atrophic. There seem to be only five cases of this kind on record in literature and in all cases nothing could be done to improve the condition.

Compulsory Gymnastics for School Children.

A circular of the Ministry of Education forwarded to all public and private schools some short time ago deals with the important question of gymnastics for all school children during and between the regular school hours. "The increase of mental work thrown upon the growing body," so says the circular, "necessitates a counterweight in shape of bodily exercise to promote circulation and removal of waste material from the organs." This sensible language is so unusual in our red-tape system that it deserves to be taken notice of. The Minister requires all teachers to institute at least four times per week a regular hour for gymnastic exercises, and as there are between 26 to 30 hours per week of mental work in school, this is not too much. Examinations of school children, conducted by the small number of school doctors at present appointed in this country, have already had the gratifying result of inducing those responsible for the welfare of the growing generation to pay special attention to questions of school hygiene. It has been ascertained that in many cases the mental overstrain had led to anæmia, to scoliosis, and to neuroses such as chorea and anorexia. Girls were found to suffer specially from such conditions, as bodily exercise is still regarded as "improper" for girls in many classes of the population. The modern trend of thought in the bureaucracy is mostly due to medical influence, as various medical men have now an opportunity of putting their up-to-date ideas into force through the medium of the Ministry of the Interior and Education.

The Question of Nurses and Hospital Attendants.

A grave breach of the rules committed by attendants in our largest lunatic asylum has caused much comment and elicited severe criticism of the system in force at the present time. It appears that a man suffering from general paralysis in its turbulent stage became somewhat noisy in the ward at night time, whereupon three attendants tried to quiet him. But their attempts were useless, so they took a wet blanket and wrapped the unhappy man in it, to render him unable to move. During these "attempts" much force and violence seem to have been applied, for the man died a few hours later, before the morning visit of the house physician. A post-mortem examination revealed a recent fracture of the larynx, besides many other injuries. Of course, the attendants were at once handed over to the police and are committed for trial for murder. But the fact that such violence is possible in a public institution has roused the indignation of the public, and in a communication to the press the managing board of the asylum tried to explain matters by stating that the male attendants came from the lower classes of the population. As a fact, the position (and pay) of hospital nurses and attendants for insane persons is generally a bad one. Only quite recently, during the last International Congress on the Care of the Insane, this question was made the subject of various papers and the complaint that the nurses were of very inferior class generally admitted to be justified. Various suggestions to improve matters have failed hitherto. But it is very likely that the above-mentioned grave incident will suffice to awaken the responsible authorities to the necessity for obtaining duly qualified nurses with adequate salaries for the patients. The last point is the *punctum saliens*, for the salary of these people is so poor that nobody is prepared to accept it if he can help it. Including all extras the fixed pay amounts to 15*s.* a week, without board. This is the real explanation of the situation and there is only one measure necessary to obtain good attendants—namely, more pay.

April 28th.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

The New Sultan and his State of Health.

THRILLING events have occurred here in rapid succession since my last letter. The formidable intrigues of the palace camarilla, the terror of the soldiers' mutiny, preceded the calm, determined, heroic invasion of the Macedonian besieging army. Then came the bombardment and bloodshed, the final deposition of Abdul Hamid, and the enthronement of Reshad Effendi under the name of Mohammed V. At last the grievously tried population of the Ottoman metropolis is able to cheer up and to look into the future with new courage and new confidence. Deep sighs of relief are heard on all sides and at every turn. The old system of tyranny and oppression, of treachery and espionage and murder, of reckless dissipation and desperate cruelty is believed by all to be at an end. The "Red Sultan," for 33 years the dread and scourge of his nation, is exiled to ancient Salonica, which will, in the historic annals of the Ottoman people, be probably regarded as the birth-place of Turkish liberty and the grave of Turkish despotism. Amid all the late events one thing stands out—the admirable behaviour of the army. Resolute and intrepid, they accomplished their end and brought about, without unnecessary bloodshed, a situation which should now develop on uninterrupted and rational lines. The new Sultan is fully cognisant of what he and his people owe to this self sacrificing courage, though he himself does not possess the necessary qualities of a strong monarch The long life of utter seclusion and privation has, it is feared, sapped his energies and reduced his vitality to a deplorable degree To lovers of constitutional government this may seem so much the better for his country and his people, as the parliamentary government of Turkey will henceforward be able to act more freely The new Sultan s health gives cause for anxiety He is said to suffer from Bright's disease and gout I saw him on several occasions and was struck by his extremely sluggish manner of moving and talking His eyes are suffused, his face is puffy and the expression of his look is vague and sad His whole figure, somewhat stoutish and curved speaks of mental and physical suffering He looks his 63 years He is reputed to be of a very kindly disposition and a friend of European civilisation He is fond of the English, writes verses in Persian, and plays the piano with considerable skill In his long seclusion he read many scientific books and frequently also books on matters of medical and surgical interest He is said to be fond of physiological experiments The population received his accession to Othman's thrône with enthusiasm

The Wounded and Dying

The Hamidié Hospital is filled with wounded and dying soldiers officers, and volunteers who fought at the last fierce encounter with the regiments of Abdul Hamid Almost every available place in the hospital is taken and the beds in each pavilion are very close to one another One room is reserved for the severely wounded another for hopeless cases a third for the merely exhausted or those who have sustained but slight injuries Almost all the soldiers have been struck with bullets either in the feet or the legs The officers, however, have wounds in the head and chest The Turks are good patients, they smile in their suffering One of the nurses of the hospital met with a tragic death She was struck by a bullet which traversed the verandah in front of the building and penetrated the pavilion where she was attending to the wounded The hospital Sourp Agop of Pancaldi above Pera has accommodated about 30 soldiers who sustained grave injuries during the fierce assault on the barracks of Taxim and Tash Kizla where a detachment of the deposed Sultan's troops refused to surrender to the besiegers The great hall of this hospital has acquired a historic interest as the national hero, Enver Bey, one of the originators of the constitutional movement, conducted from this place the command of the attack in person

April 30th

NOTES FROM CHINA

(FROM OUR OWN CORRESPONDENT)

Ningpo Mission Hospital

SOME fine records of work are shown in the reports of various mission hospitals and one cannot but be impressed with the wide field there still is in China for surgical and medical research From the twenty second annual report of the above hospital which is supported by the Church Missionary Society and is under the charge of Mr A F Cole, it appears that during 1908 there were 636 in patients, 11,857 out patients and 358 operations Out of 67 operations on the eye 50 were for entropion, a trouble to which the large eyelids of the Chinaman, coupled with the wide spread prevalence of chronic granular conjunctivitis make him specially liable One case is mentioned of bilateral elephantiasis of the vulva and there were three cases of congenital absence of the anus There were also three double amputations for symmetrical gangrene I have referred to the queries received from time to time as to possible openings for medical work in China The following paragraph in the Ningpo Mission Hospital report shows that there is at least one place where help would be welcomed —

' In the early part of the year an attack of blood poisoning contracted whilst operating on a baby with cancrum oris laid me aside for a time and the experience of that time, together with the subsequent weakness made me long for a colleague there would seem very small hope of such a man being sent at present so many places calling for reinforcements The hospital is in possession of an x ray apparatus which has been much in use

Symmetrical Gangrene

In the three cases referred to above Mr Cole could find no demonstrable cause One was a girl aged five years, with gangrene of both feet Another was a man, an actor, aged 35 years, with no history of exposure or syphilis, &c , on whom likewise a double amputation was performed The third case, a boy of 14 years of well to do family and no history of exposure, was the worst His fingers were unaffected but gangrene appeared in both feet, the back of each calf the mid tibial regions, the front of both patellæ, the helix of each ear, the tips of the shoulders and elbows, malar eminences chin and both lips The lower lip separated, as did also the lower portions of the legs leaving the bones exposed necessitating a double amputation Blood films showed a double infection of tertian malaria A good recovery was made which seemed to date from the commencement of quinine There was no hæmoglobinuria or albumin in any form, no evidence of cardiac disease or senile endarteritis, nor a history of diseased grain or ergotism in any of the three cases In Mr Cole s opinion the condition is evidently due to some toxic agent acting directly upon the nerve supply of the arterioles, causing tonic contraction of the arterioles There are vegetable toxic agents in China of which very little is known except that they cause gangrene No suggestion of these could be found in these three cases Dr A A MacFadyen of Su chou fu writing last July to the *China Medical Journal* inclosed specimens of weeds widely used by natives as a vegetable, which are said by them to poison about one out of every 100 that eat them He noted great swelling of the head and hands but no intestinal symptoms They developed high fever and then a superficial gangrene, limited strictly to the exposed parts of the body Under the clothing there is no œdema or gangrene—a fact made more striking by a few cases where the clothes had been worn open and gangrene appeared on the breast to the same extent With regard to Mr Cole s cases I might add that Ningpo is a large town on the banks of a river surrounded by an alluvial plain intersected by canals and irrigating ditches for the cultivation of rice for which the fields are kept flooded from June to the end of October Its temperature ranges from an absolute maximum of 98° to a minimum of 45° F On the whole the foreign population has good health, but the native population suffers much from diarrhœa and dysentery malarial fever being also very prevalent among them

The Leper Home at Tung Kun South China

This institution is under the charge of Dr J J Kuhne, and was established near the site of a Chinese leper settlement which had fallen into a bad state There is an average of 125 inmates During the past year of 38 adult lepers who died 26 were affected with tubercular or skin leprosy, with an average duration of life, after the disease began of 12 years, while that for the 12 others affected with nerve leprosy was 10½ years The fact that leprosy is contagious, but not hereditary, was proved by the Commission in India, and this view is further supported by Dr Kuhne who asked 167 lepers and found that 56 had a clean family history In three cases a great-grandfather was a leper, in another a grandmother in 13 a brother and sister, in five the father or mother in six although the parents were affected it was easy to trace how the disease was communicated The most striking case was that of a leper whose father became infected at 80 years of age, he had lived with his son, who had been ill 12 years without taking any precautions The two drugs which have been found of any service are alphozone and nastin The former is the favourite drug of the lepers and in addition to its value as an intestinal antiseptic in the cases of dyspepsia diarrhœa and dysentery (which are usually of bad omen and a sign that the intestine is affected) it seems also to exert a tonic influence Injections of nastin in cases of nerve leprosy have on the whole effected an improvement though it has not been a uniformly successful drug In several cases the injections were followed by headache and giddiness Leprosy exists all over China not to any great extent in the North but in Central and South China it is frequently met with While lepers in most places are allowed to roam free there are settlements here and there in which they are segregated but never strictly so The native sovereign remedy for the disease consists of the leaves of *Xanthium strumarium* The Chinese describe five different forms of leprosy. In one the skin dies, indicated by loss of sensation; in the second the flesh dies and no pain is felt in cutting it; in the third the blood dies and ulceration and pus are formed; in the fourth the tendons die and hands and feet drop off; in the fifth the bones die, the nose is destroyed, and the eyes, throat, and lips become involved. They ascribe as causes, climate, infection, defective nutrition, and the air of graves. In addition to the Tungkun Hospital there is also a leper asylum supported by the London Missionary Society at Hiao Kau in Central China which has no lack of patients.

The Tainan Hospital.

In the island of Formosa, opposite Amoy, there is an active hospital. The operations performed here during the past six years were 6250, of which 2173 were on the eye, and there were 2400 in-patients last year. Dr. J. L. Maxwell, senior, places a plea for a colleague among the first of his needs; he feels the stress of operation work from 8 to 12 or 1 o'clock daily in addition to the many other duties. Among a series of interesting cases he mentions an instance of the transition from the old to the new ideas attended by serious consequences. In adjoining beds were two patients, one still under the sway of old superstitions and the other prepared for the adoption of new methods. One, the father of the other, had fallen ill and the remedy demanded was human flesh. The dutiful son therefore took a hatchet and chopped off a finger to satisfy his father's needs and came to hospital to have the stump healed.

Peking, April 14th.

Obituary.

THOMAS WILLIAM NUNN, F.R.C.S. ENG.,

CONSULTING SURGEON TO MIDDLESEX HOSPITAL.

Mr. Thomas William Nunn, whose death we announced in a former issue, was born at Royston, Herts, in 1825 of parents belonging to the Society of Friends. He was educated at King's College, London, among a distinguished group of contemporaries, when Fergusson was still a prominent teacher, and Nunn himself took a part in the work of the anatomical department before transferring his energies to the medical school established at Middlesex Hospital, when the famous anatomy school of William and John Hunter in Windmill-street ceased to exist. In 1846 he qualified M.R.C.S. Eng., obtaining his Fellowship 11 years later. Mr. Nunn passed on to the surgical staff and continued in charge of the general wards and those set apart specially for the treatment of cancer till 1879. In an early part of his career he published observations on anatomy, amongst which was a pamphlet illustrating the natural division of main arteries into what he termed segmental and trans-segmental branches for the supply of the proximal and distal segments of the limbs respectively. Later publications were largely on the subject of cancer, in which he took the keenest interest and which he had special opportunities of observing. After retiring from active participation in hospital work, Mr. Nunn, as consulting surgeon, published accounts of 1000 cases from the cancer wards in book form. He was also consulting surgeon to the Central London Throat Hospital and to the London Hospital for Skin Diseases, a past vice-president of the Pathological Society of London, and Medical Associate of King's College, London. Mr. Nunn was at one time a lieutenant of the 3rd Middlesex Militia and honorary surgeon-major (V.D.) of the Volunteer Forces.

As a teacher he was deservedly popular, and his old pupils still refer affectionately to "Tommy Nunn," who lightened their labours with his good humour and facilitated their comprehension of difficult matters by his skill as a draughtsman and frequent colloquial expressions. Eminently practical and always kind, Nunn set a fine example in dealing with patients who were likewise his friends in the days when medical teaching was perhaps less academical than it is to-day. His association with Middlesex Hospital was maintained by his continued attendance at committees and again and again as chairman at convivial gatherings. Perhaps his last prominent appearance was as the central figure in a photograph of the medical staff taken in the hospital garden as recently as the end of 1908. Those who had known him well marked the change which recent years had wrought in him, and though he survived the winter, he suffered in the spring from the prevailing epidemic of influenza, attended chiefly by gastric symptoms, and succumbed to sudden heart failure shortly after removing to his country seat at Kneesworth at the ripe age of 84 years.

Mr. Nunn was twice married, first to Isabella, daughter of Mr. Kenneth Macleay, of Newmore, Ross-shire, and secondly to Rosalie, daughter of Mr. George White, of Kensington, who survives him. He had no children. The interment took place in Royston cemetery on April 19th.

SEPTIMUS GIBBON, M.B. CANTAB., M.R.C.P. LOND.

Dr. Septimus Gibbon, whose death was recently announced, was the son of William Gibbon, a medical man of Kettering, and was born in 1825. He was educated at Cambridge, being a scholar of Clare, whence he graduated M.B. in 1851. From 1851 to 1852 he was resident medical officer to Addenbrooke's Hospital and he became a Member of the Royal College of Physicians of London in 1852. In addition he studied at St. Bartholomew's Hospital, and during the Crimean war he went out with Miss Florence Nightingale and her nurses, being placed in charge of the British hospital at Smyrna. After serving for one year he returned to London and obtained the appointment of assistant physician to the London Hospital. He was also sanitary officer to the Hospital for the Paralysed and Epileptic in Queen-square, and in addition was for nearly 40 years medical officer of health of the Holborn district. At one time he was lecturer on natural philosophy at St. Bartholomew's Hospital and physician to the Royal Insurance Company. He did not write much, but in 1855 he contributed a paper to the *Medical Times and Gazette* on the Complications of Continued Fever. We have said enough to show that this veteran of the profession was a man of wide and varied experience, one of a class which is nowadays getting more and more rare owing to the enormous increase in the detail of every part of medicine, which practically entails that every prominent medical man must be more or less of a specialist.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Ludwig Laqueur, formerly professor of ophthalmology in the University of Strasburg, who was in his seventieth year, having retired some two years ago. He was a pupil of von Gräfe in Berlin and of Liebreich in Paris. For a time he practised in Lyons, where he was lecturer on ophthalmology in the preparatory medical school, but when the Franco-German war broke out he had to serve in the German army. Subsequently he was appointed extraordinary professor in the newly established University of Strasburg, becoming full professor with charge of the eye clinic in 1876. His chief original papers, published mostly in ophthalmological journals, dealt with glaucoma, sympathetic eye affections, refraction anomalies, and the action of atropine and physostigmine.—Surgeon-General Dr. Kaether, the oldest medical officer in the German army, has died at Aix-la-Chapelle, aged 93 years.—Dr. Richard Fleischer, formerly professor of medicine in the University of Erlangen, aged 60 years. He published a good many monographs besides a large text-book on medicine of which some of the volumes have not yet appeared.—Dr. Galvagni, professor of clinical medicine in the Modena Medical School.—Dr. Moissenet, formerly physician to the Paris hospitals.—Dr. Maurice, formerly physician to the Versailles Hospital.

ULSTER HOSPITAL FOR CHILDREN AND WOMEN.—At the annual meeting, held on April 23rd, of the supporters of this institution it was reported that during the year 1908 284 children and 102 women were treated as in-patients, while in the extern department there were 726 women and 2312 children (including 412 eye cases). There were ten intern maternity cases and 257 extern. Help in the form of food, medicine, or clothing was afforded to 30 of the maternity cases. Financially, the income was £1175 2*s.* 9*d.* (exclusive of a bequest invested of £1296 17*s.*), while the expenditure was £1133 1*s.* 2*d.*, leaving a credit balance of £42 1*s.* 7*d.* A sum of £5774 7*s.* has been promised for rebuilding the hospital, but it has been wisely decided not to undertake the work until the amount reaches at least £10,000.

Medical News.

CAMBRIDGE UNIVERSITY.—The following degrees were conferred on April 29th:—

M.D.—A. W. Wakefield, Trinity; S. Gooding, St. John's; E. E. Glynn, Clare; W. F. Buckle, Gonville and Caius; and R. A. Clapham, Emmanuel.
M.B., B.C.—M. W. B. Oliver, Trinity.
B.C.—A. W. D. Firth, Trinity.

Professor Sims Woodhead has been re-appointed the representative of the University on the Council of the Lister Institute of Preventive Medicine.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Justus Bödeker, *privat-docent* of Psychiatry, has been granted the title of Professor.—*Breslau:* An Otological Clinic has just been established with 24 beds and a lecture theatre capable of accommodating 60 students. This is the third university otological clinic established in Prussia.—*Cologne* (*Medical Academy*): Dr. Franz Dautwiz, senior staff surgeon in the Prussian army and lecturer in medicine, also Dr. Dreesmann, surgeon to the St. Vincent Hospital, have been granted the title of Professor.—*Gottingen:* Dr. Max Voit of Freiburg has been recognised as *privat-docent* of Anatomy.—*Gratz:* Dr. Walter Schauenstein has been recognised as *privat-docent* of Midwifery and Gynæcology.—*Heidelberg:* Dr. Knauff, Professor of Hygiene and Forensic Medicine, will retire at the end of the current session.—*Jena:* Dr. Hermann Dürck of Munich has been appointed Professor of Pathological Anatomy in succession to Professor M. W. Mullen, resigned.—*Kiel:* The honorary Doctorate of Medicine has been conferred on Professor Johanna Mestorf, the venerable lady director of the Schleswig-Holstein Antiquarian Museum, in consideration of her valuable prehistoric anthropological researches. She is retiring from the post she has held for very many years on her eightieth birthday.—*Lemberg:* Dr. Wilold [illegible] *docent* of Pathological [illegible] fessor of Forensic [illegible] of the kingdom of Italy.—*Vienna:* Dr. Egon Ranzi has been recognised as *privat-docent* of Surgery.

UNIVERSITY OF OXFORD.—The following dates of examinations have been announced:—Examination for M.Ch. Degree: The examination for the Degree of Master in Surgery will commence at 10 A.M. in the medical department at the museum an Thursday, June 24th. Names must be sent in to the assistant registrar at the University Registry not later than 10.30 A.M. on Friday, June 4th. The statutable fee (£5) and the required certificates must be given in at the same time. Examination for the D.P.H.: The [illegible] at separate examinations, but no one will be deemed to have [illegible] Part II. unless he has satisfied the [illegible] Part I. The fee for each part [illegible] and fees must be sent in not [illegible] day, Oct. 26th, to the assistant registrar, from whom all particulars can be obtained.

LIVERPOOL SCHOOL OF TROPICAL MEDICINE.—The Incorporated School of Tropical Medicine gives instruction in tropical medicine for the diploma in that subject which is granted by the University of Liverpool, and the period of instruction lasts for three months. Two of these courses are given in the year, the one from Jan. 6th to April 5th, and the other from Sept. 15th to Dec. 13th. In the summer there is held the short course which lasts from June 1st to June 30th. At the end of this short course an examination is held and a certificate of satisfactory attendance is granted to those who pass the examination. This certificate excuses holders from attendance during the first four weeks of the full Lent and autumn courses, one of which is necessary for the diploma. The short course has been specially designed for those medical men who are at home on leave and who have not the time to attend the full course for the diploma. It consists entirely of practical and clinical laboratory work given at the University laboratory and at the Royal Southern Hospital. During this short course the instruction on parasitology will be given by Dr. J. W. W. Stephens and that on medical entomology by Mr. Robert Newstead. The course also includes instruction in the microscopic diagnosis of malaria. The fee for the course is 4 guineas, and applications to attend it are to be sent to the Dean of the Medical Faculty, University of Liverpool. The fee must be paid in advance to the secretary of the school, B 10, Exchange Buildings, Liverpool.

UNIVERSITY OF LONDON.—A course of eight lectures on the "Structure and Functions of the Central Nervous System" will be given in the Physiological Institute of University College by Dr. W. Page May on Tuesdays at 5 P.M., beginning on Tuesday, May 11th. These lectures are open to all students of the University of London, also to qualified medical men on presentation of their cards.

THE GLASGOW UNIVERSITY CLUB, LONDON.—The members of this club will dine at the Trocadéro Restaurant on May 25th at 7.30 P.M. The Right Hon. Alexander Ure, K.C., M.P., Lord Advocate, will take the chair. Members who intend to be present or to introduce guests are requested to give notice as early as possible to Mr. W. Craig Henderson, 2, Paper-buildings, Temple, London, E.C.

THE annual meeting of the Children's Country Holidays Fund will be held at the Whitehall Rooms, Hotel Metropole, on Tuesday, May 18th, at 4.30. H.R.H. the Duchess of Albany will preside. The speakers will include the Right Hon. the Earl of Erroll, the Right Hon. Herbert Samuel, M.P., the Lord Bishop of Stepney, and Mrs. Scharlieb, M.D.

ROYAL SANITARY INSTITUTE. — A provincial sessional meeting of the Institute will be held at the Council Chamber, Guildhall, Norwich, on Saturday, May 22nd, at 11 A.M., when a discussion will take place on the Special Features of the Travis Hydrolytic Systems of Sewage Tanks Constructed for Norwich. The discussion will be opened by Mr. Arthur E. Collins, M.Inst.C.E., city engineer, Norwich. The chair will be taken at 11 A.M. by Mr. H. D. Searles Wood, F.R.I.B.A., chairman of the council of the Institute.

CHELSEA HOSPITAL FOR WOMEN.—By the kind permission of Mary Countess of Ilchester, a concert in aid of the Chelsea Hospital for Women will be held in the Garden Ball Room at Holland House, Kensington, on Friday, June 11th, at 3 P.M., when the gardens at Holland House will be thrown open to the audience. Tickets, price 21*s.* and 10*s.* 6*d.*, can be obtained from the Countess of Ilchester, Holland House, Kensington, W., the Viscountess Esher, 2, Tilney-street, W., Mrs. Fenton, 27, George-street, Hanover-square, W., and the secretary, Chelsea Hospital for Women, Fulham-road, S.W.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the Council held on May 4th the following examiners were elected for the ensuing year:—*Court A.*—For Conjoint Licence, Diploma in Public Health, and *Preliminary*—Anatomy: Alexander Fraser and Bertram C. A. Windle. Surgery: Charles A. K. Ball, Alexander Blaney, F. Conway-Dwyer, and Robert J. Harvey. Physiology and Histology: Denis J. Coffey and E. L'Estrange Ledwich. Pathology and Bacteriology: Arthur Hamilton White. Midwifery and Gynæcology: Frederic W. Kidd. Biology: John J. Burgess. Ophthalmology: Arthur H. Benson, Herbert H. B. Cunningham, and Herbert C. Mooney. Sanitary Law and Vital Statistics: Matthew J. Russell. Engineering and Architecture: James H. Fergusson. Languages: William Kennedy. Mathematics, Physics, Dictation, and English Essay: J. W. Tristram. *Court B.* — Fellowship, Licence in Surgery (for registered practitioners), Licence in Midwifery (for registered practitioners), and Licence in Dental Surgery—Anatomy: Alexander Fraser and Edward P. McLoughlin. Surgery: Charle[illegible] F. Conway-Dwyer, and Le[illegible] Histology: Denis J. Coffey [illegible] Pathology and Bacteriolog[illegible] r Hamilton White. Midwif[illegible] W. Kidd. Chemistry and [illegible] Robert J. Montgomery. [illegible] y: George

M. P. Murray and William 'G. Story. Mechanical Dentistry: Daniel L. Rogers and Edward L. Sheridan.

The King has sent a present of linen to the Chelsea Hospital for Women.

A Dorset Centenarian.—William Butler of Newtown, Branksome, has recently completed his hundredth year.

The German Society of Orthopædic Surgery has elected Professor Joachimsthal as president during the coming year, and the German Surgical Society has elected Professor Bier of Berlin as its next president.

Mr. Frederick Weatherly, M.R.C.S. Eng., L.S.A., J.P., of Portishead, Somerset, who has entered his ninetieth year, has just resigned the position of chairman of the Long Ashton board of guardians. Mr. Weatherly was coöpted as second vice-chairman.

Donations and Bequests.—The Brompton Hospital for Consumption has received from Washington cheques for $1000 (£200) and $500 (£100), representing the prizes awarded to the hospital and the Frimley Sanatorium at the recent International Tuberculosis Congress.—Mr. John Coles of Tiverton has given another £1000 to the funds of the Tiverton (Devon) Infirmary.

London School of Tropical Medicine.—The number of students desirous of taking out the course at the London School of Tropical Medicine has increased so rapidly that the accommodation of the school has been strained to its limits, and the committee regrets that it is unable to accept any further students for the present course, though in special cases application may be made to the director in case a vacancy has occurred. There is still room for students who desire to take out the advanced courses. The next session will commence on Oct. 1st.

Midwives Act Committee. — The eleventh meeting of the Departmental Committee appointed by the Lord President of the Council to consider the working of the Midwives Act was held at the Privy Council Office on May 5th, Mr. Almeric W. FitzRoy, the clerk of the Council, presiding. Evidence was tendered on behalf of the British Medical Association by the following witnesses: Mr. J. Smith Whitaker, medical secretary of the Association; Mr. C. E. S. Flemming, Bradford-on-Avon; Dr. L. S. McManus, Wandsworth; and Dr. J. H. Taylor, Salford.

Poor-law Medical Officers' Association of England and Wales.—The annual general meeting of this association is to take place this year on July 6th at the Guildhall, London, and a conference will there be opened on the Report of the Royal Commission with regard to Poor-law Medical Relief. The Lord Mayor has promised to open this conference at 11 A.M. in the Council Chamber of the Guildhall. All Poor-law medical officers in England and Wales are invited to attend and any desiring to read papers at the conference should send abstracts of such papers to the honorary secretary of the association, Dr. M. Greenwood, 243, Hackney-road, London, N.E.

The Notification of Glanders: An Exemplary Penalty.—According to a *Times* report, on May 3rd Sir A. De Rutzen at Bow-street police court completed the hearing of nine summonses against the London Parcels Delivery Company, Limited, and their superintendent, George Clawpett, charging the company with contravening the Notification of Glanders Order, 1907, by failing to give notice to the local authority or the police of the presence of one diseased and eight "suspected" horses in certain of their stables. In our issue of March 13th we reported an inquest on the body of Charles Edward Davis, a horsekeeper, who was found to have died in St. Thomas's Hospital from glanders. This man had been employed by the defendants, and in the present prosecution it was given in evidence that since his death all their horses have been examined and 200 slaughtered. The defence raised was the difficulty of diagnosing the disease in animals not suspected of it, several veterinary surgeons deposing that a horse which reacted to mallein might work for several years and never show any signs of glanders. The magistrate held the defendants to blame in not having called in veterinary aid sooner than they did, and fined each defendant the maximum penalty of £20 on four of the summonses and 1*s.* each on the other five, a total of £80 5*s.*; and he ordered the company to pay £26 5*s.* costs. There is little doubt that this salutary judgment was based on the unfortunate death due to the outbreak. It should serve to bring home to the owners of stables the dangers of disobeying an order framed in the necessary interests of public protection.

Royal Institution.—The annual meeting of the members of the Royal Institution was held on May 1st, Sir James Crichton-Browne, treasurer and vice-president, being in the chair. The annual report of the committee of visitors for the year 1908, testifying to the continued prosperity of the institution, was read and adopted, and the report on the Davy Faraday Research Laboratory of the Royal Institution, which accompanied it, was also read. 48 new members were elected and 63 lectures and 19 evening discourses were delivered in 1908. 936 volumes were added to the library in the year. The following gentlemen were unanimously elected as officers for the ensuing year: President, the Duke of Northumberland. Treasurer, Sir James Crichton-Browne. Secretary, Sir William Crookes. Amongst the managers elected were Sir Thomas Barlow, Bart., Dr. Donald William Charles Hood, Sir Francis Laking, Bart., and the Right Hon. Sir John Fletcher Moulton; and amongst the visitors Dr. William Arthur Brailey, Dr. James Mackenzie Davidson, Mr. John William Gordon, Dr. James Dundas Grant, Sir Philip Magnus, and the Hon. Charles A. Parsons.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Budget.

The Budget, which was brought in by the Chancellor of the Exchequer on Thursday, April 29th, engrosses the attention of Parliament. Its readjustment of the scheme of taxation proceeds on lines which must necessarily cause considerable controversy. In fact, it promises to be the great dominating issue of the session. There are proposals in the Budget with regard to the death duties, stamps, licence duties, and the taxation of land which will undoubtedly receive a very critical and prolonged examination from the Opposition. To professional men one of the most vital parts of a Budget is the income-tax. This year a further step in the direction of graduation and differentiation is taken. The rates upon the earned income of persons whose total income does not exceed £3000 are to remain at 9*d.* in the £ up to £2000, but are to be 1*s.* in the £ for the amount between £2000 and £3000. Large incomes and unearned incomes, which have been paying 1*s.* in the £, will have to pay 1*s.* 2*d.* in the £. A super tax of 6*d.* in the £ comes into operation in the case of incomes exceeding £5000, but in this case an abatement on £3000 will be allowed. One of the proposals of Mr. Lloyd George in regard to the income-tax at least will enjoy a wide measure of popularity. A person whose income does not exceed £500 is to be permitted a special abatement of £10 in his assessed income for each child he has under the age of 16 years. In one part of his Budget the Chancellor of the Exchequer makes a differentiation for medical men. He proposes a new tax on motor-cars, but medical men are only to pay half the tax that other possessors of cars are to be called upon to contribute. The motor-car tax is to be graduated according to the horse power of the vehicle. The tax on cars under 6½-horse power is placed at 2 guineas. Cars of 26-horse power are charged 6 guineas, but the tax rapidly rises on vehicles of the highest power. A 60-horse power vehicle will pay 20 guineas, but a car over that power will have a charge of 40 guineas placed on it. Funds derived from this source will go to the improvement of roads.

Accidents in Mines.

An interesting discussion arose on the subject of accidents in mines in the House of Commons on April 28th. Mr. Glover brought forward a demand that the staff of mine inspectors should be augmented to secure the more rigorous application of the laws affecting mining. The reply of Mr. Herbert Samuel, who spoke for the Home Office, was deemed so satisfactory that no division was taken on the subject. The gist of it was that if the Royal Commission on Mines reported in favour of an increase of the staff of inspectors the Home Secretary would have no hesitation in pressing on the Treasury the necessities of the situation. In the course of his speech Mr. Samuel pointed out that in France and in Belgium the percentage of deaths in mines was slightly less than in this country, and further expressed the belief that the irreducible minimum of fatal accidents had not been reached here.

Medical Officers of Health.

Mr. Bowerman's Bill relating to housing of the working classes contains a clause dealing with the position of county medical officers of health. It lays down that every county council shall appoint a medical officer of health, that he shall only be removable from office with the consent of the Local Government Board, that he shall not be appointed for a limited time only, and that he shall not engage in private practice nor hold any other public appointment without the express written consent of the Local Government Board.

Street Accidents in Scotland.

At the instance of the Lord Advocate a return has been ordered by the House of Commons showing for Scotland the number of accidents resulting in death or personal injury known to the police to have been caused in streets, roads, or public places by vehicles during the year ended Dec. 31st, 1908. A somewhat similar return is being compiled for England and Wales under the supervision of the Home Office.

The Royal Commission on the Poor-laws.

Amongst the papers just issued by the Royal Commission on the Poor-laws is one on the overlapping of the work of voluntary general hospitals with that of medical relief. The report on Ireland has also been published. The literature on the relief of distress which has been compiled at the instance of the Commission is becoming most voluminous. Even those Members of Parliament who devote most attention to the topics which the Commission investigated have difficulty in keeping themselves informed of the main features of these reports. There is no likelihood that legislation will be brought forward in respect to the Poor-laws and the relief of distress until next year. Time will thus be given to Members interested to master the facts set forth in the documents published by the Commission.

HOUSE OF COMMONS.

WEDNESDAY, APRIL 28TH.

Consumptive Passengers on Board Ship.

Mr. [illegible] Trade whether he was aware [illegible] Montreal and Quebec for Glasgo[illegible] the second class several person [illegible] seeing [illegible] companies that in [illegible] deck cabins only [illegible] infection was possi[illegible] isolated?

Mr. TENNANT: That is not in accordance with our information, but I will make further inquiry.

The Royal Commission on Sewage Disposal.

Mr. CARLILE asked the [illegible]

The Poor-law Commission in Scotland.

Mr. GULLAND asked the Prime Minister when the report of the Poor-law Commission dealing with Scotland would be issued.—Mr. ASQUITH answered: I am not in a position at this moment to give any definite information.

Malta Fever amongst the Civil Population.

Mr. LUPTON asked the Under Secretary of State for the Colonies what was the number of cases of Malta fever, and also of simple continued fever, which had occurred among the civil population of Malta during each of the years from 1897 to 1908 inclusive.—Colonel SEELY furnished the following written reply: The number of cases of Mediterranean fever and of simple continued fever in the years mentioned is as follows:—

Year.	Mediterranean fever.	Simple continued fever.
1897	568	107
1898	510	125
1899	822	114
1900	642	80
1901	624	60
1902-3 (financial year) ..	589	66
1903-4 " " ...	573	35
1904-5 " " ...	663	26
1905-6 " " ...	822	22
1906-7 " " ...	714	42
1907-8 " " ...	501	5
1908-9 " " ...	463	11

THURSDAY, APRIL 29TH.

Poor-law Medical Officers in Scotland.

Mr. CATHCART WASON asked the Lord Advocate whether he would state what parish councils in Scotland had opposed granting to Poor-law medical officers protection against arbitrary dismissal, and also the same privileges as were enjoyed by medical officers in England and Ireland.—Mr. URE furnished the following written reply: The proposal has not, so far as I am aware, reached a stage which has provoked the active expression of opinion on the part of parish councils. On this point I can add nothing to the reply recently given to my honourable friend.

Mr. WASON also asked [illegible] position.—Mr. URE answered: I am not aware of [illegible] benefit the poor.

Beri-Beri amongst Lascars.

Mr. COOPER asked the President of the Board of Trade [illegible]

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE CHILDREN ACT AND PUBLIC HOUSES.

ACTS of Parliament frequently produce results in directions quite unexpected. It would be impossible to quarrel with the motive of Section 120 of the Children Act, which seeks to exclude children under 14 years of age from the interiors of public-houses. But if references, serious and humorous alike, which we have read in the daily press have any foundation, it has been pitiable recently to see crowds of children left standing outside the public houses in the bitter evening winds, while their parents and guardians were regaling themselves in the warm bar. It is claimed that the new Act will protect children, among other evils, from undue exposure to night air, but this loitering of children outside public-houses will do much to counteract any such tendency for good. In country places where space is available the matter can, no doubt, be gradually dealt with by the provision of proper outside shelters, and this point can probably be safely left in the hands of the licensing justices, for it is evident from questions asked of the Home Secretary in the House of Commons that the justices are in general disposed to require alteration in construction of licensed premises to meet the requirements of this Act. Unless some movement is made in this direction, the exposure of children, thus hanging motionless about street corners, must be very prejudicial to general health. Further, the licensing authorities would do well to consider the provision of proper sanitary accommodation suitable for children of either sex, in view of the probability of crowds of children being thus detained for perhaps long periods of time, otherwise unpleasant violations of public decency must occur, as much of the existing accommodation in public-houses would not be accessible to children under the requirements of the Act.

A CURIOUS CAUSE OF FOOT SORENESS.

To the Editor of THE LANCET.

SIR,—The following case may be of interest as showing an unsuspected cause of "sore feet." A woman of 40 complained of heat and soreness of the soles of the feet. Her occupation compelled her to be on her feet the greater part of a 16-hour day, and she noticed that towards evening the pads of the soles under the toes became acutely painful and hot. Along the line of greatest friction and pressure was a layer of indurated skin, the soft pads above being very sore and hot, causing a sensation as though spicules of glass were imbedded in it. On careful examination numerous worsted hairs were found projecting from the skin, requiring the patient use of fine forceps for their withdrawal. *The removal of these hairs and a change to cotton stockings* removed a cause of lameness and fatigue which had existed for years

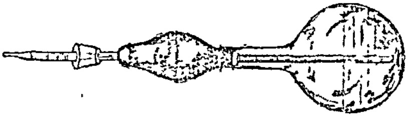
I am, Sir, yours faithfully,

LÆTITIA H. ANDREW-BIRD, L.R.C.P. Irel.

De Beauvoir-road, N., May 1st, 1909.

AN AMPOULE FILLER.

IN THE LANCET of March 27th we printed a note on the advantages and method of using ampoules. Messrs. Chas Zimmermann and Co. have forwarded to us a short account of an ingenious appliance by which these glass receptacles may be filled with a sterilised fluid. The *contrivance is known as the Elias Fountain Bulb. It consists mainly* of an elastic bulb connected with a tight-fitting central glass tube forming a cap or stopper. The lower part of the bulb (which fits to the neck of the bottle or flask) is provided with air channels or perforations communicating with the interior of the vessel, so as to exert pressure on the liquid therein when the bulb is squeezed by the hand. The dispenser sterilises the liquid to be ampouled in a flask or other convenient vessel, and by pressing the rubber bulb the liquid contained in the flask may be forced through the glass tube directly into the ampoule without fear of contamination.



THE EMMANUEL MOVEMENT IN AMERICA.

To the Editor of THE LANCET.

SIR,—During a brief stay in London the writer has become aware of a certain confusion existing in the minds of people between the Emmanuel movement in America and what is known as the Emmanuel Society, the methods and aims of which respectively are quite distinct.

It should be clearly understood that the Emmanuel movement in America, which began three years ago under the leadership of Dr. E. Good Worcester, rector of Emmanuel Church, Boston, in coöperation with some of the leading neurologists of that city, is not a faith healing movement as that phrase is commonly understood. It does not undertake the cure of any and all diseases, but only those of a nervous or functional character. In this specialising of its efforts to alleviate suffering it is not limiting the power of God, but attempts the humbler task of learning His will as embodied in the ascertained facts known to medical science as the laws of health and disease.

Hence it does not act independently of, but in constant reliance upon and coöperation with, medical men. No case is taken for treatment unless first diagnosed by a competent physician, preferably a neurologist, who recommends it as likely to yield to the psychical and religious methods employed by the clergymen engaged in the work.

With few exceptions, the leading physicians everywhere in America have welcomed this movement and given it their warmest support. No fees are charged by the clergy, who feel amply rewarded in the larger opportunity for service to their kind, and especially in the reconstruction of moral and spiritual character which the treatment almost invariably effects.

I am, Sir, yours faithfully,
ALBERT B. SHIELDS, A.M. Harvard,
Superintendent and Chaplain of St. Luke's Hospital,
San Francisco, Cal., U.S.A.

WANTED, A HOME.

To the Editor of THE LANCET.

SIR,—Can any of your readers tell me of an institution into which a woman, practically helpless from a paralytic seizure, aged 62 years, can be permanently received? She has 10*s.* a week, which represents the extent to which she could contribute towards her maintenance. I am, Sir, yours faithfully,

(MRS.) M. FIRTH.

8, Church-circle, S. Farnborough, Hants, April 27th, 1909.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

TUESDAY.

SURGICAL SECTION (Hon. Secretaries—Herbert F. Waterhouse, Walter G. Spencer): at 5.30 P.M.

Papers:

Mr. J. Hutchinson: Auto inoculation and Reinfection of Syphilis.

Mr. Herbert J. Paterson: Jejunal and Gastro-jejunal Ulcer following [illegible] Notes of Two Cases, in One of wh[illegible] made Before and After Operation [illegible] ith an Abstract of 59 Recorded Cases and Observations thereon.

THURSDAY.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION (Hon. Secretaries—H. Beckett-Overy, William J. Gow): at 7.45 P.M.

Short Communication:

Mr. J. Bland Sutton: Red Degeneration of a Uterine Fibroid, Associated with the Staphylococcus Pyogenes Aureus.

Specimens:

Specimens of Ruptured Uteri will be shown by the President, Dr. W. E. Fothergill, Dr. H. Russell Andrews, Dr. J. B. Hellier, and others.

Papers:

Dr. T. W. Eden: The Operative Treatment of Rupture of the Uterus; with an Account of Three Cases treated by Abdominal Hysterectomy.

Dr. Lionel Smith: The Treatment of Rupture of the Uterus; with a Description of Cases.

FRIDAY.

CLINICAL SECTION (Hon. Secretaries: Raymond Johnson, H. D. Rolleston): at 8 P.M.

Cases:

Dr. F. Spicer: Paralysis of Spinal Accessory Nerve.

Mr. W. G. Spencer: Reduction of an Old Subcoracoid Dislocation of Shoulder, Complicated by Fracture of Humerus, by Excavating the Glenoid Cavity.

Dr Finzi: (1) Inoperable Recurrent Carcinoma of Mamma treated by Radium; (2) Epithelioma of Lip under Treatment by Radium; (3) Arthritis of the Knee treated by Lithium iodine Ionisation.

Mr. V. Warren Low: Pneumococcal Cystitis and Arthritis.

Mr. Sidney Boyd: A Patient with Sprengel's Deformity of the Shoulder and Hirschsprung's Disease (Definite Rectal Obstruction).

Dr. McNalty: Aortic Aneurysm (?) in a Boy.

Dr. Parkes Weber: Woman Three Years after Omentopexy and Drainage for Chronic Ascites probably connected with Hepatic Cirrhosis.

Dr. F. de Havilland Hall and Mr. W. G. Spencer: Splenectomy for Splenic Anæmia.

(At 9 P.M.):

Dr. T. Stacey Wilson will show Three Coloured Projection Drawings of the Brain, showing the Relations which the Internal Structures would be seen to have to the Convolutions if the Brain were Transparent.

Paper (at 9.45 P.M.):

Dr. Poynton and Mr. Trotter: A Case of Cardiolysis with a *resumé* of the Operative Measure Practised.

N.B.—Fellows of the Society are entitled to attend and to speak at all Meetings.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8 P.M., General Meeting. Election of Officers for 1909–10 Session and Reports of the Various Committees and Council. 8.30 P.M., Mr. J. D. Malcolm: The Treatment of Shock.—Mr. T. H. Kellock: The Association of Appendicitis and Pyosalpinx.

UNITED SERVICES MEDICAL SOCIETY, Royal Army Medical College, Millbank, S.W.

WEDNESDAY.—8.30 P.M., Major H. W. Grattan, R.A.M.C., and Captain D. O. Hyde, R.A.M.C.: Some Points in the Standardisation of Typhoid Vaccine.

HARVEIAN SOCIETY OF LONDON, Stafford Rooms, Titchborne-street, Edgware-road, W.

THURSDAY.—8.30 P.M., Dr. H. J. Macevoy: Paroxysmal Pulmonary Œdema in Bright's Disease.—Dr. B. H. Spilsbury: Some Practical Points in Clinical Bacteriology.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. S. E. Dore: Clinique (Skin). 5.15 P.M., Lecture:—Dr. T. D. Savill: T[illegible]

TUESDAY.—4 P.M., Dr. G. Ranki[illegible] M., Lecture:—Mr. T. Walker: [illegible] of Malignant Disease of the Bladder.

WEDNESDAY.—4 P.M., Mr. C. Ryall: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. C. O. Hawthorne: The Scope and Purpose of the British Pharmacopœia.

THURSDAY.—4 P.M., Sir Jonathan Hutchinson: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. F. J. Wethered: The Treatment of Chronic Heart Disease, especially by Mechanical Methods.

FRIDAY.—4 P.M., Dr. S. Spicer: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Lecture:—Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Pathological Demonstration—Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eyes. 2.30 P.M., Operations. 5 P.M., Lecture:—Dr. Davis: Diseases of Throat, Nose, and Ear.

TUESDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Moullin: Gynæcological Cases.

WEDNESDAY.—10 A.M., Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Saunders: Diseases of Children. 12.15 P.M., Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Harman: Diseases of the Eyes. 2.30 P.M., Operations. Dr. Robinson: Diseases of Women. 5 P.M., Lecture:—Dr. Beddard: Medicine.

THURSDAY.—10 A.M., Lecture:—Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eyes. 2.30 P.M., Operations. 5 P.M., Lecture:—Dr. Davis: Diseases of Throat, Nose, and Ear.

FRIDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. Lecture:—Medical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Low: Plague.

SATURDAY.—10 A.M., Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Saunders: Diseases of Children. Mr. Harman: Diseases of the Eyes. 12.15 P.M., Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. 2.30 P.M., Operations. Dr. Robinson: Diseases of Women.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. H. Evans). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. W. Carson); X Rays. 4.30 P.M., Medical In-patient (Dr. A. J. Whiting).

TUESDAY.—Clinic: 10 A.M., Medical Out-patient (Dr. A. G. Auld). 2.30 P.M., Operations (Mr. Carson). Clinics:—Surgical Out-patient (Mr. W. Edmunds); Gynæcological (Dr. A. E. Giles).

WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. H. W. Carson); X Rays. 3 P.M., Medical In-patient (Dr. G. P. Chappel). 4.30 P.M., Lecture:—Mr. W. Edmunds: Knots, Ligatures, and Sutures.

FRIDAY.—10 A.M., Clinic:—Surgical Out-patient (Mr. H. Evans). 2.30 P.M., Operations (Mr. W. Edmunds). Clinics:—Medical Out-patient (Dr. A. G. Auld); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie).

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Sir Dyce Duckworth: Medicine. 3.15 P.M., Mr. Turner: Surgery. 4 P.M., Mr. G. N. Biggs: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 2.15 P.M., Special Lecture:—Sir Dyce Duckworth: Tedious Recovery from Illnesses.

TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. Carless: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. Sale-Barker: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 3.15 P.M., Special Lecture:—Sir William Bennett: The Moral Factor in Relation to the Treatment and Growth of Disease.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

[illegible]

TUESDAY.—3.45 P.M., Lecture:—Dr. Atkinson: Pharynx and Naso-pharynx.

FRIDAY.—3 45 P.M., Lecture:—Dr. D. McKenzie: External Ear.

OPERATIONS.

MO[illegible]

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

A Presidential Address
ON
THE SPREAD OF TUBERCULOSIS—HEREDITY OR INFECTION?

Delivered before the Birmingham University Medical Society

BY J. G. EMANUEL, B.SC., M.D., B.S. LOND., M.R.C.P. LOND.,
SENIOR PHYSICIAN TO OUT-PATIENTS AT THE QUEEN'S AND CHILDREN'S HOSPITALS, BIRMINGHAM.

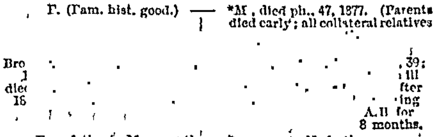
GENTLEMEN,—The title of this address indicates sufficiently, I trust, the question to which I wish to draw your attention this evening. Which is the important factor in the spread of consumption, is it heredity or is it infection? To which is due the vast army of consumptives that we are daily called to alleviate if not to cure? Is consumption kept ever with us because tuberculous parents produce tuberculous children, or because consumption spreads *from one* member of the community to another, as we know is the case with cholera, [illegible] diseases? If [illegible] it is our duty [illegible] approval on t[illegible] of tuberculosi[illegible] can only stamp out tuberculosis by the successful annihilation of the tubercle bacillus. This we are slowly effecting by teaching consumptives to destroy their expectoration and by segregating phthisis as we do patients suffering from other infectious diseases. In this difficult and protracted warfare we are helped by our Legislature, which enforces a pure air-supply to our schoolrooms, factories, and workshops, and which is endeavouring to insure a tubercle-free milk-supply to our towns and cities.

To make my thought quite clear I may say at once that, while I do not deny that both heredity and infection play their respective rôles in the spread of consumption, I am inclined to think that for all practical purposes it is the infectiousness of consumption we have to deal with, and that we may, for the most part, disregard hereditary predisposition. Or, to put the same thing in another way, I do not think that because a man dies from consumption his children are necessarily more liable to this disease than children of a non-consumptive Their liability to consumption depends upon their exposure to infection. The infectivity of consumption is in no sense a new theory. Galen wrote about it some 150 years B.C. (200-131 B.C.). The knowledge of consumption is older still. Hippocrates' classical work on the subject was written between 460–377 B.C. It was the recognition of the contagiousness of consumption that led Koch 26 years ago to discover the [illegible] It was because Koch recognised [illegible]tions that he sought for the cause [illegible] it in the form of the tubercle bacillus. The discovery of the tubercle bacillus did not start the theory of contagion. *Shortly after Koch's discovery* an attempt was made to settle the question which was the chief factor in the production of tuberculosis, heredity or infection? A general inquiry was instituted in the United States, England, Germany, France, Italy, Holland, and Russia. This investigation [illegible] briefly, I may say, because o[illegible] cally proving a case to be [illegible] infection.

The scientific proof of heredity is well-nigh an impossibility. We should require the records of many families in which several children of tuberculous parents had succumbed to tuberculosis in spite of early removal from their parents and early separation from one another, without the possibility of exposure to other sources of infection. It is quite obvious that such conditions are impracticable. Such restrictions can, however, be employed in the case of guinea-pigs and rabbits and are most nearly approached in man in orphan asylums. The results of these animal experiments and the records of orphan asylums, as will be mentioned later, give no support to the hereditary doctrine.

Let us first turn our attention to cases of phthisis occurring in the same family, because it is just these cases that give such strong support to the importance of the hereditary factor. When, however, we carefully examine these family cases we shall find: (1) that they arise by infection *carried by one member of the family to another* and are in no sense the result of hereditary influence; (2) children hereditarily tainted tend to remain healthy when brought up in orphan asylums or foundling institutions; (3) in many cases of phthisis among children the disease can be traced to the foster-parents or to the step-parents and not at all to the parents themselves; and (4) often the parents show the first signs of disease years after the birth of the child, and very often the parents and children fall victims at about the same time. A detailed consideration of a few of these cases will help to make these points clear.

CASE 1.—

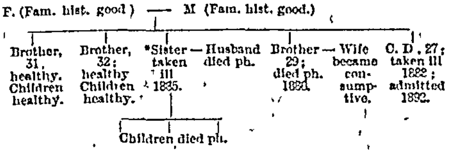


F. (Fam. hist. good.)
*M., died ph., 47, 1877. (Parents died early; all collateral relatives
Bro
died
16
39;
ill
fter
ing
A.B. for
8 months.

F. = father. M. = mother. * = source of infection.
A. B., C. D., &c. = patients. Ph. = phthisis.

A. B., aged 31 years, was admitted into hospital in 1892. The family history on his father's side was good, but his mother died from phthisis in 1877, aged 47 years, and all her collateral relatives died from the same disease. One year after the death of the mother in 1878, a brother, aged 16 years, died from phthisis; he had always lived at home. In 1879, a sister, aged 25 years, who had been married for three years, died from phthisis; she had been sick ever since leaving her parents' home. In 1883 a brother, aged 18 years, died from phthisis. In 1887 a brother, aged 35 years, died; he was said to have suffered from cough and expectoration for years A. B. first showed symptoms in 1889. The brothers and sisters had associated together a great deal. The eldest sister, aged 39 years, nursed the patient for eight months and fell a victim in 1892, the year that he was admitted into hospital. Cases like these are frequently quoted as proving hereditary transmission of the disease from parent to child, but it will be observed that the mother showed the first signs of the disease years after the birth of her youngest child and that the children became affected all within a few years of each other at quite different ages.

CASE 2.—

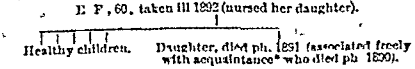


F. (Fam. hist. good.)
M. (Fam. hist. good.)
Brother, 31, healthy. Children healthy.
Brother, 32; healthy Children healthy.
*Sister taken ill 1885.
Husband died ph.
Brother 29; died ph. 1886.
Wife became consumptive.
C. D., 27; taken ill 1882; admitted 1892.
Children died ph.

In the following case the disease was brought into the *family by one of the daughters.*

C. D., aged 27 years, [illegible] but he had had hæmopt[illegible] aged 31 and 32 years, [illegible] healthy. In 1885 a married sister who had lost her husband and three children through tuberculosis became consumptive. A brother, aged 29 years, who had had much to do with this sister, died from hæmoptysis in 1886, and his wife also became consumptive C. D. had associated a good deal with his consumptive *brother and sister, and, as already* stated, had his *first symptoms of the disease in 1883.*

CASE 3.—



E. F., 60, taken ill 1892 (nursed her daughter).
Healthy children.
Daughter, died ph. 1891 (associated freely with acquaintance* who died ph. 1890).

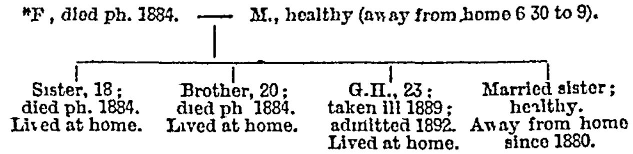
In this case the disease passed directly from daughter to mother.

E. F., a married woman, aged 60 years, had good health

No. 4472.

until 1892 when she contracted phthisis. Her family history was excellent. She had six children, five of whom were healthy and aged from 25 to 36. One daughter had associated very freely with a tuberculous acquaintance both in working and in leisure hours. The acquaintance died from phthisis in 1890, the daughter followed in 1891 a victim to the same disease, and the patient herself (who had nursed her daughter) became consumptive the following year. The other five daughters had come but little into contact with their consumptive sister and remained in good health.

CASE 4.—

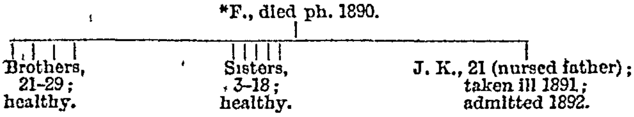


*F , died ph. 1884.
M., healthy (away from home 6 30 to 9).
Sister, 18; died ph. 1884. Lived at home.
Brother, 20; died ph 1884. Lived at home.
G.H., 23: taken ill 1889; admitted 1892. Lived at home.
Married sister; healthy. Away from home since 1880.

In the following case those who were least at home escaped.

G. H., aged 23 years, was admitted suffering from phthisis in 1892. His father died from phthisis in 1884 and during the same year a sister, aged 18 years, and a brother, aged 20 years, both died from phthisis. The patient lived with this brother and sister and in 1889 had his first hæmoptysis. His eldest sister married in 1880, left home, and remained healthy. His mother, aged 56 years, worked away from home all day (6.30 A.M. to 9 P.M.) and was also healthy.

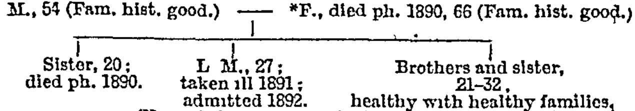
CASE 5.—



*F., died ph. 1890.
Brothers, 21-29; healthy.
Sisters, 3-18; healthy.
J. K., 21 (nursed father); taken ill 1891; admitted 1892.

J. K., aged 21 years, was admitted in 1892. Her father died in 1890 from phthisis; she nursed him until his death. In 1891 she had hæmoptysis and a year later was admitted with phthisis. Her brothers, aged 21 to 29 years, and her sisters, aged 3 to 18 years—i.e., both younger and older than she—were all healthy.

CASE 6.—



M., 54 (Fam. hist. good.)
*F., died ph. 1890, 66 (Fam. hist. good.)
Sister, 20; died ph. 1890.
L M., 27; taken ill 1891; admitted 1892. (Nursed sister at home)
Brothers and sister, 21-32. healthy with healthy families. (Away from home all day.)

L. M., aged 27 years, was admitted in 1892. Her mother was 54 years of age and was healthy. Her father died at 66 years of age from phthisis in 1890. The same year the death of her sister, aged 20 years, from phthisis occurred, and this sister was nursed by the patient. The patient became affected with the disease in 1891. The other children (21 to 32), i.e., both younger and older than the patient, are in good health and have healthy families. They remained away from home the entire day.

What I wish to emphasise with regard to these cases is that while they are cases in which different members of the same family have succumbed to the same disease, far from supporting any theory of heredity, they speak strikingly in favour of the doctrine of infection. In a given family, parents and children, young and old, all fall victims at much the same date, irrespective of their ages, thus showing that the infection passes from one member of the family to another, sometimes from brother to sister, or sister to brother, sometimes from parent to child, but not infrequently from child to parent. If, on the other hand, these were cases of heredity, we should not expect to find parent attacked in much the same year, but we should expect that the children would become affected on reaching a certain age, that age varying in different families. What actually occurs is that parent and child, or brother and sister of quite different ages, all succumb within a few years of one another.

Infection through marriage.—Heredity does not explain cases of infection through marriage, of which there are hundreds of cases on record. The infection is more often from husband to wife. Out of 262 cases collected by the British Medical Association 119 were cases of infection from husband to wife, and in 69 the infection was from wife to husband. Dr. Weber instances nine husbands, tuberculous before marriage, who lost 18 wives, one lost four in succession, one three, four two each, and three one each. The wives were all healthy before marriage and with one exception free from hereditary taint.

Infection through the dwelling.—Just as infection is transmitted in families and in married couples, so it often occurs amongst unrelated individuals accustomed to live together. The essential element in all such cases is the fact of living together. Such infection plays an especially important rôle amongst the lower classes with whom overcrowding is prevalent. The room need not be simultaneously occupied by the consumptive and another, for virulent tubercle bacilli have been found on the walls of a house six weeks after the death of an uncleanly consumptive. Two consumptives died in a new, fairly healthy dwelling, and within the next 12 years 12 fatal cases of consumption occurred amongst the occupants. The following case, which seems to be a case of house infection, came under my own notice.

In April, 1906, I saw two sisters who lived in Burton. The elder was suffering from chronic phthisis of about two years' duration, while the younger sister had acute phthisis of 12 months' duration. These were the only known cases of consumption in the family and on seeking a cause for their illness I was told the following. About three years before the elder sister had left home in perfect health to earn her living in Coventry where she lodged in the house of a widower whose wife had but recently died from consumption. Within three months of her going to this house she became affected with cough, expectoration, wasting, and night sweats and had to return home. The younger girl had never left home, and, to my mind, there is little doubt that she caught the disease from her sister, who imported it into the home from Coventry. The infection was a virulent one, for she died from her disease in December, 1906. The elder sister is still living.

Infection of fellow labourers.—The consumptive may be a greater source of danger to his fellow workman than to his family, especially in the case of indoor occupations. The mortality is much higher in the case of indoor employees (factory hands, workshop assistants, office clerks, waiters, &c.) than in the case of outdoor employees (masons, builders, coachmen, policemen, street cleaners, &c.). The following cases came under my own observation.

I examined in January, 1907, A. G., a jeweller, aged 28 years. He was then suffering from acute phthisis of the left lung and was first taken ill at Easter, 1906. His father, brothers, and sisters were in good health but his mother had succumbed to consumption 20 years ago. At first I thought "Well, this clearly is a case of hereditary transmission," but on further inquiry I elicited the following. A. G. worked in a small workshop with 14 or 15 other hands and with one of the men, P. K., he was closely associated. These two men worked at the same bench alone and they were in the habit of using in common a camel-hair brush for soldering purposes and this brush was constantly kept in their mouths. Now P. K. had a very bad cough on his first coming to the shop, and he was known to have died from phthisis in February, 1906. In my opinion this savours far more of infection of one workman by another than of transmission from a mother who died 20 years before her son showed any signs of the disease.

E. T., a seaman on H.M.S. *Implacable*, 18 years of age, had a family history free from tuberculosis, and his personal history was quite good up to the time of his entering the *Implacable* in January, 1906. In July, 1906, he became ill and in August, 1906, was discharged invalided with phthisis. I saw him in January, 1907, and he had well-marked phthisis of both lungs. He *volunteered* the information that he must have caught his cough from another seaman, W. S., who occupied a berth alongside his own. W. S. was invalided out of the service with phthisis shortly after E T. There are not sufficient data to express a definite opinion but it is highly probable that E. T. was infected either by W. S. or by one of the other seamen on board.

Infection through nursing.—It is the pride of many consumption hospitals to make the boast that their nurses and residents do not become infected. This, however, is not borne out by my own experience derived from living in one of London's large consumption hospitals for a period of nearly three years. I have met with not a few instances of

infection [illegible] sisterhood [illegible] used to be [illegible] prophylaxis it fel[illegible] This must have been due to [illegible] exposure to infection, since all other conditions remained unchanged.

Infection of health resorts.—In Cannes tuberculosis was rare among the inhabitants before 1860; from that time, which marks the beginning of the winter invasion by consumptives, the disease has become frequent. Davos, San Remo, and Mentone, originally free from tuberculosis, have had the disease gradually imported by invalids from this and other countries. In all these instances the washerwomen and the chambermaids have been the most noticeable victims. Certain people, like the Tahiti, the New Zealand, and American Indians, first learnt to know tuberculosis from Europeans, and came to regard the coughing "white man" with terror. Such facts as these can find no adequate explanation in heredity, but, on the other hand, stand out pre-eminently in support of the contagiousness of the disease.

Influence of age and sex.—It is, however, when we come to consider the influence of age and sex that the doctrine of heredity receives its greatest blow.

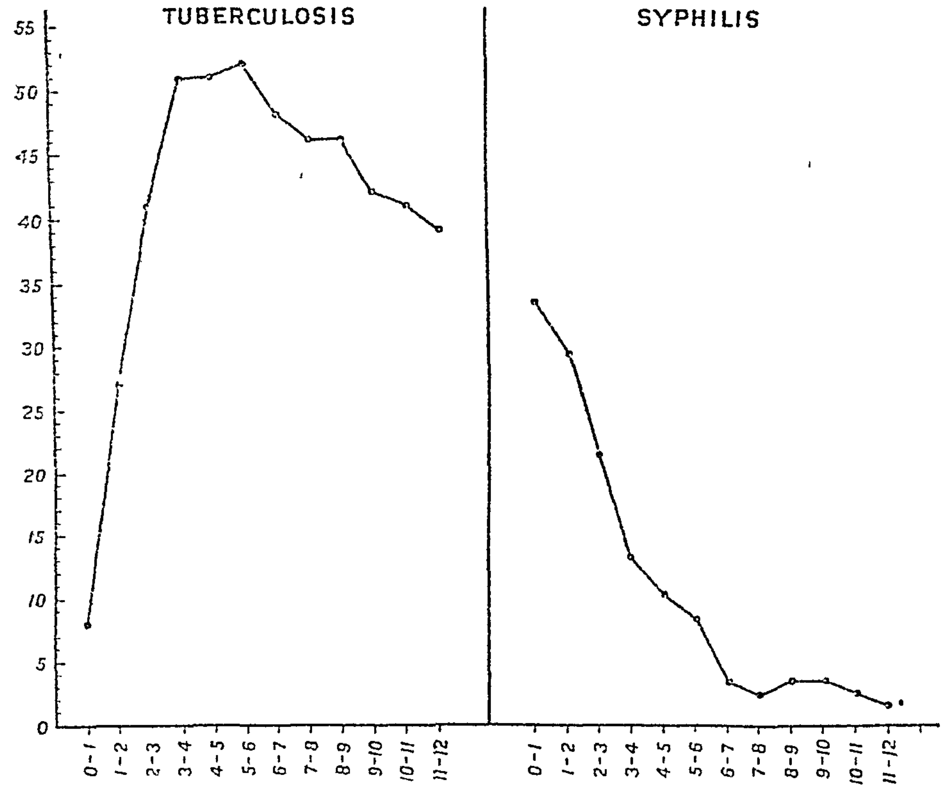
Charts 1 and 2 represent the mortality from tuberculosis at different ages and are constructed from the Registrar-General's returns for England and Wales. They cover a period of 16 years—1891–1906—and satisfy at least one of the requirements of trustworthy statistics, for they represent a mortality from tuberculosis of nearly 1,000,000 out of a total population of over 500,000,000. They include all forms of tuberculosis, general, pulmonary, abdominal, and meningeal, as well as tuberculous diseases of the glands, skin, joints, bones, &c. The charts show an enormous mortality in infancy (0–5 years); higher, indeed, than at any other period of life. The death-rate falls in the second and third quinquennium and then begins to rise till it reaches its maximum between 45 and 55, when it again declines. It will be noted that the maximum mortality does not occur, as is generally thought, in the prime of life, but at the more advanced age of 45 to 55 years. The very high mortality in infancy (0–5 years) is due, as a glance at Chart 2 will show, to the enormous death-rate in the first year of life. Chart 1 seems to show that the schools are not a great source of infection; this may be a fact, but, on the other hand, the infection acquired during the school age (5–15) may swell the mortality returns of the succeding years, for tuberculosis is a chronic disease, and the chart does not show the age of infection but the age at death. For the most part the mortality amongst males is higher than that amongst females, but from 10 to 25 it is appreciably higher in females. It may be that in females the strain of puberty and of child-bearing shows itself very markedly in those who are affected with tuberculosis. The doctrine of *heredity will not explain this table, for* if heredity were the important factor in influencing the amount of tuberculosis we should expect that the gradually diminishing *mortality observed in the first five years of life* and continued through the 5–10 and 10–15 age-periods would be continued throughout life. Instead of this we find that after reaching a minimum of 10 to 15 for males and 5 to 10 for females, it begins to rise till it reaches a maximum at 45 to 55 for males and 35 to 45 for females, when it again declines. Such a curve as this cannot be explained by any hereditary influences.

Let us now consider briefly the doctrine of heredity. It is generally conceded that the children of tuberculous parents frequently become tuberculous. This by many is ascribed to hereditary influence and while some believe that the children are born with the bacilli in their system most merely assume the transmission of a certain predisposition.

Bacillary transmission.—We will first discuss the possibility of the transmission of the bacillus to the embryo by the mother or father during its intra-uterine existence, for according to some the tubercle bacillus is present in the child at birth, but may remain latent for a varying number of years, when some temporary lowering of the individual's resistance allows the bacilli to burst into activity and cause the disease we know as tuberculosis. Now if this were so we should expect to find numerous examples of congenital tuberculosis, for theory requires that 1 in 9·5 *of all children* born should contain the germ of tuberculosis. Now for years the attention of pathologists has been directed to this question, and many thousands of stillbirths and of children under one month have been submitted to examination. What is the result? There are actually less than 20 cases of congenital tuberculosis on record.

Contrast this with syphilis which we know to be infectious and hereditary. Instances of congenital syphilis from similar post-mortem examinations are numerous beyond mention. The few cases of congenital tuberculosis that have been found have occurred in women with advanced tuberculosis who have never survived their confinements by more than a few weeks. Of the cases themselves one died three weeks old, one eight days old; the others were not even born alive, but were fœtuses of five to eight months. We may surely conclude that while congenital tuberculosis may exceptionally occur it can be of no importance as a factor in the dissemination of consumption. It may be suggested that the very high mortality already referred to as occurring in the first year of life must be due to congenital tuberculosis—i.e., that children are born with tuberculosis, active or latent, but die in large numbers, in the first year of life, just like what we know to occur in children born with syphilis. Congenital syphilis, we know, gives rise to many miscarriages and stillborn children, but of those infected with syphilis and born alive the majority die in the first year. Might this not be so in tuberculosis? I think not and for this reason. If you analyse the deaths from congenital syphilis and from tuberculosis occurring in the first year of life you will find that, whereas in syphilis—a truly congenital disease—the majority of deaths occur in the first month and month by month the death-rate diminishes (*vide* Chart III.) till it becomes almost inappreciable by the twelfth month, exactly the opposite is the case with tuberculosis. Here the minimum of deaths occurs in the first month and the death-rate rises month by month till the maximum mortality is reached in the fourth, fifth, and sixth months. This suggests that these deaths from tuberculosis are not due to a congenital disease like syphilis. The infant is born healthy and remains free in the early months of life, and it is not till some months have elapsed during which opportunities have been afforded for infection to occur that symptoms of tuberculosis show themselves.

CHART 3.



Deaths from tuberculosis and syphilis (both sexes) in England and Wales in 1906, in the first year, per 10,000 births.

9-10	4·2	0·3
10-11	4·1	0·2
11-12	3·9	0·1

Latency of tuberculosis.—Is it possible, as some hold, for tubercle bacilli to enter the embryo in utero and remain latent till adult life, when some accidental circumstance weakens the individual and renders the soil suitable for the dormant horde of bacilli to awaken into life? In support of this view is put forward the fact that in people dying from disease other than tuberculosis, tuberculous foci, partly or completely healed, are frequently found. Such accidental findings have been placed by some observers so high that in every third or fourth non-tuberculous corpse such a focus can be found. There is, however, no proof that these foci have been present for a long time. They are probably due to post-natal infections which have become healed. It seems improbable that tubercle bacilli could remain alive but latent sometimes for 40 to 60 years, when we realise that in the laboratory bacilli cannot be kept alive for more than half a year under the most favourable conditions. But all doubts as to the extra-uterine origin of tuberculosis in infancy, to say nothing at all of its occurrence in adults, are expelled by the pathological findings. In cases of tuberculosis incontestably congenital the liver is the organ chiefly involved, and this is because the germ derived from the mother is carried to the fœtus in the blood stream, and, for anatomical reasons, passes to the liver before it is distributed to the other organs. Now in the preponderating majority of tuberculous children it is not the liver, but, as in adults, the lungs and bronchial glands that are chiefly affected, and after these organs the mesenteric glands, according as the infection is by inhalation or by food consumption. The theory of heredity, however, receives another blow from the fact that the children of tuberculous parents remain free from the disease if removed from their parents, that is to say, from the source of the infection. Thus, at an orphan asylum in Munich in 41 per cent. of the children both parents had died from tuberculosis, and in 43 per cent. either the father or the mother. In spite of this only two cases of tuberculosis were observed amongst 620 children. In an orphan asylum in Nuremberg with capacity for 100 children, many with a pronounced tuberculous taint, only a single case of tuberlosis occurred in eight years Bernheim found that the progeny of tuberculous rabbits, guinea-pigs, and dogs became tuberculous if they remained with their parents, but on the other hand remained well if removed instantly after birth. It fell to this observer to deliver three tuberculous women of twins. In each case he had one child nursed by a healthy wet nurse living with the mother and the other child sent to the country. In all three cases the children at home died, whereas those sent to the country remained well.

Hereditary predisposition.—A majority of physicians understand by the term heredity when applied to tuberculosis not a bacillary transmission but a certain predisposition. The percentage of cases showing a hereditary predisposition varies widely from 10 to 85 per cent. according to different authorities. This discrepancy varies according as the parents only are taken into account, or the parents and grandparents, or in addition the sisters and brothers of the parents; by some tuberculosis occurring in any relative is regarded as a sign of hereditary taint. Hence the great variation 10 to 85 per cent, quoted by different authors. The mere fact, however, that the same disease has appeared previously in the family does not prove a hereditary predisposition.

Remembering that a given patient has on an average 12 close relatives (reckoning only two parents, four grandparents, one sister, one brother, and one brother and sister to each parent), it is not to be wondered at that more than one death from consumption is to be found in the same family, since we have seen that 1 in every 9·5 individuals dies from tuberculosis. To prove hereditary predisposition we must prove that in the families of the non-tuberculous consumption does not occur even approximately as often as in the families of consumptives. This has not yet been demonstrated. On the other hand, Kuthri tested the frequency of tuberculosis in the parents of 432 tuberculous and 108 non-tuberculous patients and found practically no difference in the amount of tuberculosis in the parents of these two classes. Even were it proved that the children of consumptives were more frequently the victims of tuberculosis than those of healthy parents, this would not prove hereditary predisposition; the greater frequency would be due to increased opportunities for infection. In order to prove hereditary influence one would have to remove the individual from the circle of his family and then exclude every possible chance of contagion from external sources—an impossible procedure. Bernheim's experiments on animals in which these conditions have been fulfilled have already been quoted. Before assuming a hereditary transmission from parent to child one must exclude the possibility of infection of the parent by the child. Not infrequently the disease is transmitted by the child to the parent.

s in young people heredity
part, whereas in the consump-
strangers is more commonly
noticed. This is simply because when consumption appears in young people, infection generally is to be found in the family circle, while in adults separation from the family is the rule and the disease is more readily traceable to contact with strangers. Some observers make a point of the greater frequency of hereditary transmission through the mother. But again all that this means is, that the mother being in more intimate relation with the children and the home than is the father, contagion has a better chance of spreading from the mother to the child than from the father to the child. Surely, it may be urged, some people are more liable to consumption than others. Yet, on the other hand, can there be any sharp distinction between those that are susceptible to tuberculosis and those that are immune from it, when we consider that 1 in 9·5 of all persons dies from tuberculosis, and that tuberculous foci are found in numerous other bodies as well? Susceptibility or no susceptibility, the healthiest and strongest individuals with no hereditary taint fall victims to consumption. It is only necessary to recall the prevalence of consumption in athletes and of tuberculosis in prize cattle.

In conclusion, let me make it clear that I have no desire to ignore the part that heredity may play in the spread of consumption. I only wish to emphasise the fact that infection exerts a far greater influence. Heredity cannot explain:—1. Cases of phthisis occurring in the same family and obviously spreading from one member to another. 2. Cases of phthisis conveyed from husband to wife and *vice versâ*. 3. The prevalence of phthisis among the overcrowded poor. 4. The greater prevalence of phthisis among in-door as opposed to out-door employees. 5. Cases of phthisis occurring amongst individuals brought into close contact by their daily avocations, either in the home, office, workshop, or factory. 6. The prevalence of phthisis among those engaged in tending consumptives. 7. The appearance of phthisis in places now used as health resorts, previously immune from the disease. 8. The mortality from tuberculosis gradually diminishing from infancy to 10 to 15 years and subsequently rising to a maximum at 45 to 55 years.

I give prominence to what I call the "infection" factor chiefly because of its great practical importance in directing our campaign against tuberculosis. It should also exert a cheering influence, for society need not brand as dangerous those of its members in whose family some relative may have died from this disease. And yet this is constantly done. We see it in the examination for life insurance. As soon as an individual applies to insure his life, if there is any consumption in his family, he is made to pay a high premium if he be not actually refused; whereas another applicant with a good family history is passed as a first-class life, though he may be daily exposed to infection either at home through his wife and children or at his daily work. Such an individual is far more likely to fall a victim to tuberculosis than one who may have lost a near relative through this disease. This attitude adopted by insurance companies is one that reflects the views of the public, and I may say that it was just this knowledge that prompted the subject of this address.

Why the hereditary factor, which no doubt exists, falls into insignificance in the case of tuberculosis is difficult to answer, but it may be that the very prevalence of tuberculosis is the reason. No one speaks of the hereditary transmission of measles and scarlet fever, though it is more than probable that these infections have a predilection for certain families. These diseases are so prevalent that we only concern ourselves with their paths of infection and not at all with any theoretical consideration of the possibility of their hereditary transmission. This may be the same with tuberculosis. Tuberculosis is so prevalent that any hereditary tendency to it falls into comparative insignificance. From the practical point of view it is the various paths of infection that are of importance to us and not the hereditary predisposition to the disease.

THE X RAY TREATMENT OF RINGWORM OF THE SCALP,

WITH SPECIAL REFERENCE TO THE RISKS OF DERMATITIS AND THE SUGGESTED INJURY TO THE BRAIN.

BY J. M. H. MACLEOD, M.A. ST. AND., M.D. ABERD., M.R.C.P. LOND.,

PHYSICIAN FOR DISEASES OF THE SKIN, VICTORIA HOSPITAL FOR SICK CHILDREN, CHELSEA; ASSISTANT PHYSICIAN FOR SKIN DISEASES, CHARING CROSS HOSPITAL, LECTURER ON DERMATOLOGY, LONDON SCHOOL OF TROPICAL MEDICINE.

The x ray treatment of ringworm of the scalp has attracted considerable attention recently on account of (1) the deliberations of the London County Council on the desirability of providing medical treatment of certain specified diseases in the Council's school children and the suggestion that the x ray treatment should be employed in the case of ringworm; and (2) the alarming statements which have been made in the press that this treatment might injure and arrest the development of the growing brain. In this contribution I propose to give my experience of this treatment since October, 1904, with special reference to the risks associated with it. Since 1904, in the out-patient departments under my charge and in private I have treated or personally supervised the treatment of over 370 children, and with the exception of a few cases in 1904 treated by multiple doses, all these cases have been treated by the single dosage method based on the principle introduced by M. Sabouraud—namely, of exposing the affected areas of the scalp at a distance of 15 centimetres from the anticathode, and employing circular localisers of various sizes, and in this way over 1500 single doses have been given.

Everyone with any extensive experience of the treatment of ringworm of the scalp will agree that the x ray treatment, if successfully carried out, is the most rapid, effective, and painless method of curing the disease. It is true that a small isolated patch of ringworm of the scalp may be quickly cured by skilful needling with croton oil in the manner advocated by Dr. H. Aldersmith or by electrolysis of the diseased hairs, but when the disease is extensive such methods are not practicable. A considerable experience of the older methods of treatment in two out-patient skin departments previously to the introduction of the x ray method showed the great difficulties of curing the disease by parasiticide and irritating applications. In my own experience I regarded it as most fortunate if an extensive case was cured under a year and in a large number of the cases the time of attendance at hospital extended to several years. This was doubtless partly due to the treatment being carried out at home in a perfunctory manner, but at the ringworm school at Paris under the charge of M. Sabouraud where the affected children lived and were under constant supervision and thorough treatment by the most effective remedies then known, the average time in which a child was cured was 18 months.

By the x ray treatment, under favourable conditions and successfully carried out, a case of ringworm, however extensive, may be cured in three or four weeks and without causing either pain or discomfort to the child, and by it the average time of residence in the ringworm school has been reduced from 18 months to three months. Before the use of the x rays the average cost per child in the ringworm school at Paris was 2000 francs; by means of the rays the cost has been reduced to 260 francs. At the ringworm schools of the Metropolitan Asylums Board, under the care of Dr. T. Colcott Fox, a corresponding reduction in the time of treatment has been achieved, and according to the report in 1906, by the employment of the x rays the time taken to cure a case has been reduced from an average of 18 months to three and a half months. It is unnecessary to labour this point further than to say that since the introduction of the x rays for the treatment of ringworm of the scalp a disease which was formerly the opprobrium of physicians can now be cured in a comparatively short time, provided the scalp is not in an inflamed condition from the application of irritating ointments.

In this paper I do not intend to discuss the mode of application of the x rays for ringworm of the scalp but will simply state the method employed in the two out-patient skin departments under my charge. In 1904 in the first few cases which I treated I employed the multiple dosage method, but abandoned that in 1905 for the single dosage method which I regard as being not only far more accurate and practical but safer, since with repeated small doses an accumulated effect may take place in an uncertain manner. Since 1905 the dosage of x rays which I have employed has been regulated by the Sabouraud and Noiré pastille, which I have found invariably to be reliable. The tube stand and system employed was described and figured in the *British Medical Journal* in September, 1905, and by means of it the pastille can be turned to the standard tint in an average of 15,000 dips of the mercury break in about 15 minutes, with a tube of a tension of 6 to 7 of the Benoist radiochronometer and about half a milliampère of current in the secondary circuit. Localisers of the required length and diameter are used and the whole of the affected area is exposed piecemeal, each area after exposure being accurately covered with thin sheet lead. After the exposure a 3 per cent. salicylic acid and sulphur ointment is rubbed all over the scalp each night and in the morning a carbolic and glycerine lotion (1 in 8) is applied; on the fourteenth day, and during the third week, while the hair is falling out, the scalp is washed every morning in addition. The exposed areas should be completely bald by the twenty-first day, and the child no longer infectious. The hair begins to grow again in a fine down six weeks later, and the regrowth is complete in five or six months. The new hair is strong and healthy; it may be lighter in tint than the older hair or it may be of a darker hue, but it gradually becomes indistinguishable from it. Occasionally it comes in more curly than it was formerly. This, in short, is the sequence of events when the x rays are successfully employed, but unfortunately the operation is exceedingly delicate and difficult. It requires not only experience in adjusting the x ray system to do the work, but it necessitates great care in matching the pastille and entails a thorough knowledge of the disease to enable the operator to map out the scalp so as to include every diseased hair in the exposure.

The chief causes of failure with the method are: (1) Under exposure, accidental or intentional where the scalp has been irritated, so that an imperfect defluvium of the hair takes place and infected hairs are left; (2) omission of a focus of disease in the exposure; and (3) insufficient thoroughness in the after treatment so that infection takes place of unexposed areas as the hairs are falling out.

Certain risks have been cited from time to time in association with this treatment, of which the following are the most important: (*a*) Severe dermatitis followed by permanent baldness; (*b*) permanent baldness without obvious dermatitis; and (*c*) suggested injury to the underlying brain. With regard to these, my experience is confined to the single dosage method—namely, the employment of what may be designated as a Sabouraud pastille dose.

(*a*) *Severe dermatitis followed by permanent baldness over the affected area.*—So far as my own experience goes, I have had only one case of severe dermatitis followed by baldness over a circular exposed area. This unfortunate experience occurred in 1905 in the initial period. The case had been previously treated with iodine, which might partially account for it. Since these early days in 1905 I have had no further unfortunate experience of this nature. There are several possible causes of this accident, but the most common is over-exposure from failure to match the pastille or the use of wrong pastilles; the other causes are the exposure of an area which has been previously irritated by remedies such as iodine or chrysarobin before the inflammation has completely subsided, the use of too large a localiser so that the convex portions of the scalp are too near the tube, the overlapping of exposed areas in a restless child, or the regulation distance of the scalp from the anticathode not being preserved. It might happen, too, through mistake that one of the areas was exposed twice.

It has been asserted from time to time that idiosyncrasy plays an important part in this connexion. This factor in my experience has been greatly exaggerated, and I have been fortunate in not having met with a definite instance of it so far, but one competent authority has told me of a case. It is probably true that fine fair hair requires a smaller dose to bring it out than coarse dark hair, that the hair comes out somewhat more easily in the occiput and about the nape of the neck than in the vertex, and that the delicate hair of a child of four years of age comes out more readily than that of a child of 12 years, but my experience has been almost invariably that an imperfect defluvium has resulted when I have purposely under-exposed a scalp or a part of it. With the apparatus employed running so that a dosage of 15,000 dips of the break is required to turn the pastille there would seem to be, as a rule, a slight margin of safety which compensates for any idiosyncrasy, and if in an individual instance 14,000 might be a sufficient dose to cause the defluvium the extra 1000, though it may cause a transient erythema and bring out the hair more rapidly, does no permanent harm, so that in practice I invariably give a full Sabouraud dose. It would seem, then, that with the single dosage method severe dermatitis is simply the result of over-exposure or of not adhering to the regulation distance of the scalp from the anticathode of the tube—namely, 15 centimetres—and that it ought not to occur. Of course, accidents may happen to anyone and mistakes may be made by the most careful operator, but with proper care these should be most exceptional.

(*b*) *Protracted or permanent baldness without marked dermatitis.*—Cases have occurred in which the regrowth of the hair was much delayed or in which permanent baldness had occurred in the exposed area without any marked inflammatory symptoms. In such cases a cicatricial atrophy of the part occurs with impairment or destruction of the hair papillæ. This is also doubtless due in most cases to over-exposure. I have so far not met with such a mishap, the only instance approaching it being an unfortunate experience in which a small area, of about the size of a shilling, in the centre of a large exposed patch has remained permanently bald. *This occurred like the accident referred to above in* 1905 and was caused by the central convex portion of the exposed area being too near the tube, to the danger of which I was not sufficiently alive at the time. Other instances of this accident may have occurred in my practice of which I am unaware, as it is impossible to follow up all of one's hospital cases and occasionally patients cease to attend as soon as the hair begins to grow again. It has always seemed to me strange that protracted or permanent baldness should not have occurred more often out of the 1500 exposures, when one takes into consideration the facts that alopecia areata not infrequently follows ringworm in the scalp and that this disease seems in many cases to succeed an apparently slight nervous disturbance. The fact that this accident rarely happens shows that the action of the x rays in pastille doses on the hair papillæ is comparatively slight, simply temporarily suspending their function for a few weeks.

(*c*) *The suggested risk of injuring the brain.*—Even if the risks of producing dermatitis and permanent baldness by this mode of treatment were many times greater than they are, it would be a small matter in comparison with injury to the underlying brain were that proved to take place; and if it were definitely established that the treatment by the single dosage method properly carried out resulted in permanent nervous symptoms or in arrest of development, the treatment, in spite of its advantages, would have to be discontinued. This fear, which is a perfectly natural one, and must have occurred to every one employing the treatment, has been fostered in the lay mind by all manner of vague statements, and even by alarming letters in the daily press.

Being alive to such possibilities I have so far avoided exposing a child under three years old, where the skull is very thin and the fontanelles not closed, but I am told on excellent authority that it is perfectly safe to expose even infants. I have closely watched my cases from this point of view and have tried to obtain reliable data on the subject from others who employ the method so as to find out on what these alarming statements have been based. Up to the present time my experience and inquiries on this point have been negative. A search through the literature dealing with the subject has not revealed a case in which injury to the brain or arrest of development has been proved to have directly resulted from the treatment properly applied. It is possible that such cases may exist, and for obvious reasons not have been published, but in the public interest it is of the greatest importance that such unfortunate experiences should be made known to the medical world. On questioning on the subject several of my colleagues who are in charge of skin departments and employ the x ray treatment by the single dosage method I have invariably received answers in the negative. In my own cases I have never seen nerve symptoms suggesting the slightest injury to the brain or arrest in development. By the actual exposure no sensation is produced, and children if placed comfortably on a couch frequently go to sleep during it and wake up fresh and bright. Occasionally on questioning the mother one has been informed that the child complained of a slight headache and was restless for a few hours afterwards, but as a rule this is not the case, and it can be reasonably attributed to the noise and sparking of the apparatus, to the confinement in the hot room for several hours while a number of areas were exposed, and to excitement and fright in the case of a young nervous child. It is not uncommon to find that young children are frightened at first by the noise and sparking, and it may take considerable time and patience to get them quieted down so that they will remain still during the exposure. No sensation is complained of until about the fourteenth day, when the part becomes itchy and feels hot, and a faint erythema may be noted just before the defluvium begins; these symptoms disappear in a few days and no further sensations are experienced. In hospital practice there are great difficulties in following up all the cases but this does not obtain in private practice, and if brain effects had supervened it is most probable that one would have heard of them, and even if they had occurred from some other cause the x rays would possibly have been blamed for them. In several cases boys have been x-rayed a year or more before going up for important examinations, such as the naval examination, and the treatment did not prevent *their passing successfully. In a recent letter* which M. Sabouraud wrote to me on the subject he made the following statement which he has kindly permitted me to quote: "I have never seen any nervous trouble, either passing or permanent, or any arrest of development following applications of the x rays made on the scalp with the dosage employed for the cure of ringworm. This is my opinion after five years' continuous experience, employing the applications daily, and having treated in this manner about 3000 children." This important statement of M. Sabouraud, whose experience probably exceeds that of any-one else, speaks for itself.

It has been stated that nervous derangements, though they do not show themselves about the time of the exposure, may do so at some remote period and may be delayed until the [illegible] shown signs of trouble by this time. There is a consideration, however, which seems to me to argue strongly against the possibility of such a delayed accident, and that is the fact that in connexion with the skin where late developing and slowly progressive dermatitis has occurred, going on to epitheliomatous changes, it has been due to repeated exposure to the rays over a long period. In the case of a single exposure such as is employed for ringworm, on the other hand, the effect manifests itself, if at all, in a fortnight and passes off in a few days, unless the exposure has been excessive, when the effect may appear earlier. That the effect of the exposure to a single full dose is transient is shown not only by the disappearance of the erythema but by the fact that the inhibition of the function of the hair papillæ passes off and regrowth of the hair takes place, and late after-effects do not occur. If these are the effects of a single dose on the skin, which is directly exposed to the rays, the effects on the brain ought to be analogous, only modified so as to be greatly reduced owing to the brain being screened from the rays by the scalp and skull. And if from an exposure to a full dose, or even from a single over-exposure, no signs of brain trouble manifest themselves at the time when an inflammatory reaction might be expected to occur in the meninges—i.e., about the third week—there does not seem to me to be any reason for suggesting that brain symptoms might develop at some remote period, and, so far as I am aware, there is no evidence to that effect.

In what has been stated above all the evidence against the suggested injury to the brain has been of a negative character. So far I have not been able to obtain any positive evidence, and only vague statements have been forthcoming, the foundation of which I have been unable to ascertain. With the object of attempting to settle the matter on a firmer basis than that of negative evidence I have done the following series of experiments which, though not absolutely conclusive, are still of interest in this connexion.

Believing the Sabouraud and Noiré pastille to be a reliable index of the maximum dosage of x rays to which the skin may be subjected without harmful consequences, and knowing that dosage to be sufficient to cause the defluvium of the hair from the exposed areas without so injuring the papillæ that regrowth is prevented, and having found the pastille as supplied and standardised by Drault to be invariably reliable, if used according to Sabouraud's directions, I have employed the pastille in these experiments as a means of [illegible] x rays which can penetrate [illegible] A piece of fresh scalp and the [illegible] ll of a boy ten years old were obtained and employed to screen the pastille from the x rays in the following three experiments. In almost every case the pastille had a piece of thin lead sheeting placed behind it. The exposures were given by the x ray system already referred to, the apparatus being kept running so that the pastille was turned after an average of 15,000 dips of the break as indicated by the speed counter. During the time of the exposure the pastilles were usually covered by a dark velvet cloth, and they were compared with the standard tint in diffuse daylight.

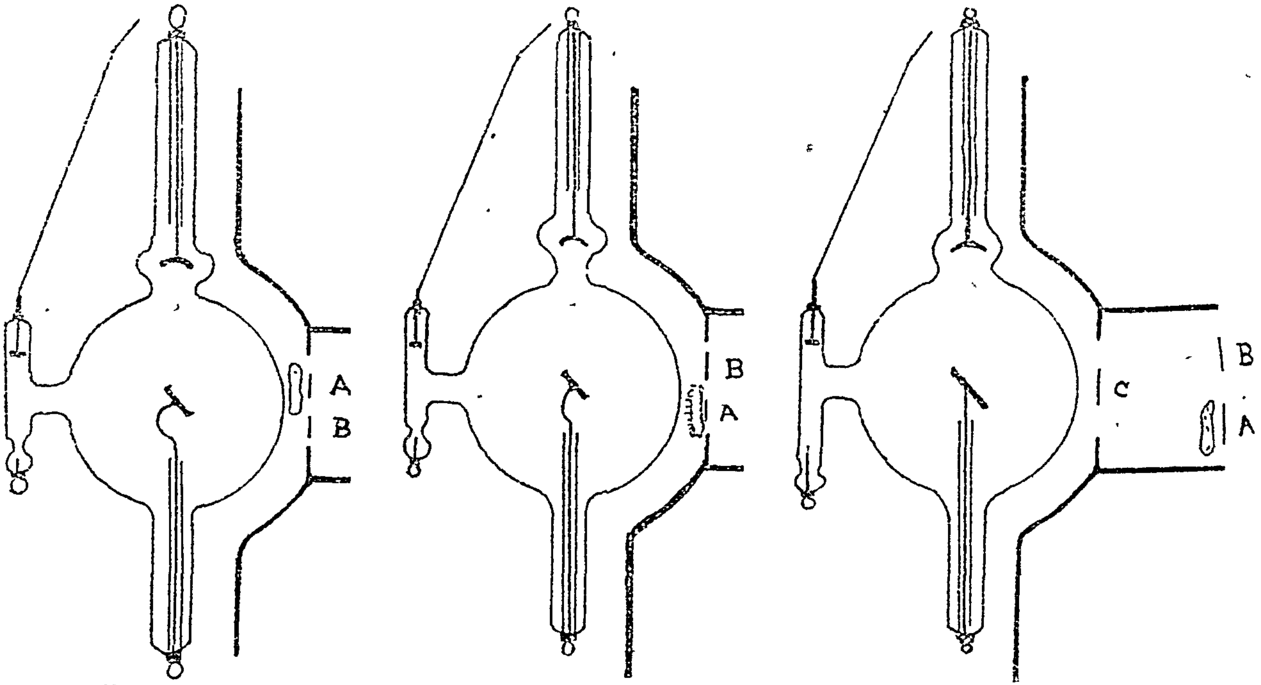
Experiment 1.—In this case a pastille (A) was placed behind the thinnest portion of the parietal bone which was found to correspond in its screening capacity to a layer of aluminium 2 millimetres in thickness, another pastille uncovered (B) being placed alongside as a control. These were both placed at the regulation distance for the pastille, namely, 7½ centimetres—i.e., half the distance of the scalp from the anticathode. It was found that to turn pastille A to the required tint it was necessary to expose two uncovered pastilles B; in other words, that at a distance of 7½ centimetres from the anticathode the thinnest portion of the parietal bone allowed only half the quantity of effective rays to reach the pastille. Pastille A was turned to the standard tint after two pastilles had been exposed at B in 23,000 (the large number being due to the tension of the tube being low at first) and 15,000.

Experiment 2.—In this experiment the conditions were similar to those in Experiment 1, except that a piece of fresh scalp was employed in place of the piece of bone in the case of pastille A. At a distance of 7·5 centimetres pastille A was turned with an exposure of a dose and a half. Pastille B was turned in 13,000 dips of the break, while pastille A required 20,000. The protection afforded by the scalp was such that only about two-thirds of the rays passed through it.

Experiment 3.—In this experiment three pastilles were exposed. Pastille A protected by the layer of bone at a distance of 15 centimetres from the anticathode—i.e., the regulation distance of the scalp—pastille B at the same distance uncovered, and pastille C uncovered at a distance of 7·5 centimetres. Pastille A was turned to the standard tint by 6 pastille doses as indicated at C. Pastille B was turned after 3⅝ pastille doses as indicated at C. This experiment verifies the fact that the effect of the rays on the tissues varies inversely with the square of the distance and emphasises the vital importance of invariably exposing the skin at the same distance. The action on the bone-protected pastille A was slightly more than half that on the uncovered pastille at the distance of 15 centimetres, and did not quite correspond to the result in Experiment 1 where both pastilles were exposed at 7·5 centimetres, but it also showed that the thinnest piece of bone in the skull was in itself sufficient to protect the underlying tissue, so that only about a half of the effective rays reach it. Pastille A turned to standard tint after the exposure of 6 pastilles at C, with the number of dips of the break, 15,000, 15,000, 15,000, 15,000, 15,000, and 14,000. Pastille B turned to standard tint after exposure of 3⅝ pastilles at C, with the number of dips 15,000, 15,000, 15,000, and 10,000.

In these experiments the exposures were made through the thinnest parts of the parietal bone, which was chosen as being one of the thinnest parts of the skull. The amount of protection afforded by it alone was so great that only 50 per cent. of the rays passed through it. In the case of the thicker parts of the same bone the protection is considerably greater and in the thickest parts is almost absolute. The protection given by the scalp is also considerable as it seems to cut off about 30 per cent. of the rays, so that only about 20 per cent. of the x rays penetrate through the scalp and the thin parts of the skull—i.e., one-fifth of a pastille dose—and this amount of rays is still further reduced, if not wholly cut of, by the vascular meningeal membranes.

It might be argued that by the single-exposure method, when two opposite sides of the scalp have to be exposed, the cortex of the brain would be exposed twice, once to the direct exposure and once to the exposure on the other side after the rays had passed through the brain. This is an argument of no practical importance as the radiation from the other side would be greatly reduced in this passage, and when it reached the further side owing to the increased distance its effect would be negligible.



EXPERIMENT 1. EXPERIMENT 2. EXPERIMENT 3.

The letters A, B, and C indicate the position of the pastilles to which reference is made in the text.

Experiment 4.—In this experiment the thin portion of the parietal bone was fixed to the forearm of a young woman and the skin exposed to a full pastille dose at the regulation distance of 15 centimetres. In the part of the skin covered by the bone—that is, the part subjected to half a pastille dose—there was not the slightest apparent effect on the skin, no suggestion of a reaction occurred in the fortnight, nor did the delicate lanugo hairs fall out.

Experiment 5.—This experiment was of another type and consisted of inoculating on maltose-agar diseased hairs which had been subjected to a pastille dose, the stumps being epilated at varying times up to the third week when the defluvium takes place. In every instance, except where the culture had become contaminated, the inoculation resulted in the development of a typical culture of the ringworm fungus. This simply verifies the known fact that the exposure of an affected hair to a pastille dose of the x rays does not kill the ringworm fungus but simply brings out the hair. When one considers the comparative delicacy of the spores and mycelial threads of the ringworm fungus and the fact that it can be destroyed by an inflammatory reaction set up by irritants, the potency of a full pastille dose of the rays, far less a small proportion of one, on living healthy tissue would seem to be comparatively slight.

Though I am aware that in connexion with such exposure experiments certain debateable points arise with regard to the probable existence of x rays of different powers of penetration, hard rays and soft rays, and their respective action on healthy and diseased tissue, still my experience has shown that what we are mainly concerned with in the therapeutic application of the x rays is the quantity of x rays which reach the tissue, and the pastille is a simple and reliable method of estimating it. From these experiments it seems to me that the scalp and meninges so protect the underlying brain that only a small proportion of the dose of x rays, if any, can reach it. This small amount of x rays instead of doing harm may even act as a stimulant to the brain as has frequently been asserted in connexion with small doses of the rays.

In this contribution I have tried to state the position fairly after considerable experience of the method, having encountered many difficulties with it at first and having had many failures before these difficulties were overcome. Where the chief disappointments have been met with has been in the cases in which under-exposures have been given purposely or inadvertently, or where a small affected area was missed out, or where the after-treatment between the exposure and the defluvium was carelessly carried out. I have avoided discussing such questions as the relative effect of the x rays on the skin and deeper structures, such as nerve tissue, but I fully concur with the opinion that doses of x rays such as are employed in the treatment of ringworm, though they affect the skin, do not cause appreciable changes in such tissues as nerve, muscle, and fibrous tissue, which are much more resistant to the rays.

In conclusion, my experience since 1905 has led me to the belief—

1. That the x ray treatment of ringworm by the single-dosage method with the dosage regulated by the pastille is practically safe and harmless.

2. That it is a method of treatment of such delicacy that even in the hands of an experienced operator an accident such as an over-exposure might happen, but that such accidents should be of such extreme rarity as not to discredit a mode of treatment possessing such obvious advantages.

3. That severe dermatitis followed by permanent baldness is the result of an over-exposure or is due to some accident such as the exposing of an area the resistance of which has been lowered by the previous application of strong irritants before the inflammation has entirely subsided, the use of wrong or inaccurately standardised pastilles, or from overlapping.

4. That permanent baldness or delayed hair-growth without marked dermatitis is the result of over-exposure, but that it might in rare instances be due to some idiosyncrasy on the part of the patient in the same way as the occurrence of alopecia areata after ringworm.

5. Finally, I have been unable to obtain any definite evidence of injury to the brain by this method of treatment from my own cases, from the literature on the subject, or from anyone with experience of this treatment whom I have asked, and the experiments which I have done in this connexion strongly negative the possibility.

Harley-street, W.

THE HISTOLOGY OF RHEUMATIC ENDOCARDITIS.

BY CAREY COOMBS, M.D. LOND., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN, BRISTOL GENERAL HOSPITAL.

WHILE examining a number of inflamed and otherwise diseased hearts I have made sections of a dozen or more valves showing evidences of recent or old "rheumatic" endocarditis, and also of spots of mural endocarditis found accidentally during a thorough examination of the muscular walls of an acutely inflamed "rheumatic" heart. The cellular changes noted in these sections have not differed much from those usually described in text-books, but their mode of origin and sequence seems to me to be other than that often taught. The word "rheumatic" is here used to cover all cases of "acute simple" endocarditis and the valvular fibrosis resulting therefrom.

In rheumatic endocarditis we meet with both kinds of inflammatory reaction—that characterised by the formation of new cells from those already existing in the inflamed tissue, and that in which the cells "resisting" infection are imported by the circulation from other parts. Both kinds are present, but the proliferative factor is far more important and characteristic than the exudative.

In all cases of acute rheumatic endocarditis the dominant feature of the histological picture is the presence of certain cells which are almost certainly the outcome of proliferative activity in the local tissues. These cells are identical with those fully described in recent papers on rheumatic myocarditis.[1] They are larger than ordinary fibroblasts, which in their shape they resemble. Sometimes, as a result apparently of degenerative changes, they are swollen and rounded. About one-third or one-half of these cells are multinuclear, the number of nuclei not exceeding six or seven. These nuclei stain very well at their periphery and in the centre, the resulting impression being that of a sharply defined rim inclosing a clear space in the midst of which are several deeply stained dots. The cytoplasm stains deeply and uniformly, especially with basic dyes. These large cells are gathered together into groups or tracts into which other cells enter scarcely at all. In cases of destructive or malignant endocarditis groups of such cells are not seen. Their distribution in the valve is of two kinds. First, they may lie in nodules in the deeper parts of the valve or even in the centre of one of the chordæ tendineæ. In these nodules, which are especially plentiful in valves vascularised by previous inflammation, there is often a central area of slightly granular material staining well with eosin, inclosed within a ring of the characteristic cells. Secondly, they may form layers along the surface of the valve without dipping deeply into its substance; such layers correspond in area with the patches of fibrin deposited on the surface of the valve. In one valve a group of these cells lay just beneath the surface without any lesion of the endothelium.

But it is the position occupied by these cells in the patches of mural endocarditis referred to above that is peculiarly enlightening. Just as in the intermuscular connective tissue so also in that immediately beneath the pericardium and the endocardium we find nodules such as I have described in former papers.[2] These appear to express the inflammatory reaction provoked locally by the impact of rheumatic micro-organisms borne into the cardiac wall by the coronary arteries; and their histology is the same, whether they are intermuscular or subendocardial. When a nodule arises under the endocardium certain changes follow in the neighbouring area of serous membrane. My sections fortunately provide a complete series of pictures of these changes. First there is the formation of a localised patch of œdema just beneath the endothelium. Lymphocytes appear in this patch and the building of new capillaries is soon visible. [illegible] leaves an "ulcerated" surface through which a few lymphocytes escape, while upon it fibrin is heaped up, sometimes separated from the endocardial surface by a layer of leucocytes chiefly of the polymorphonuclear type. This leucocytic covering is more likely to be found in endocarditis of the ventricular recesses than on the valves, probably because the greater stagnation of the blood stream favours it. Stems of newly formed capillaries may grow out into the fibrinous mass from their endocardial roots, but the presence of fibrin is not essential to their formation.

Inflammatory exudation in rheumatic endocarditis takes the form of lymphocytosis—that is to say, one can say confidently that in rheumatic endocarditis, as in myocarditis, the majority of the leucocytes are mononuclear. They are scattered sparsely through the valve, with greater concentration at some spots; not even at such spots, however, are they densely crowded, and there seems to be no certain connexion between these more infiltrated areas and the fibroblastic zones. There is, however, another form of leucocytosis sometimes found in rheumatic endocarditis. Over those surfaces where the fibroblasts are plentiful and the endothelium stripped off polymorphonuclear leucocytes are sometimes deposited freely, especially on the patches of mural endocarditis. Judging from appearances, these are derived from the blood passing through the cavities of the heart, for they are plentiful on the endocardial surface but are scarcely found at all beneath it. We may therefore draw a contrast between the moderate diffuse lymphocytosis seen in all cases of rheumatic endocarditis and the intense but localised polymorphonuclear leucocytosis seen on surfaces which have lost endothelium; in the first the cells come from the coronary blood, in the other from the intracardiac blood.

---

[1] Brit. Med. Jour., vol. ii., 1907, p. 1513; Quarterly Journal of Medicine, October, 1908.

[2] Ibid.

The changes that remain after acute inflammation has cooled down can be summed up in two words—fibrosis and vascularisation. The valve is thickened chiefly but not solely at its free edge; the proximal part near the attachment of the flap is found thickened at any rate in the more advanced fibroses. New vessels are sown plentifully throughout, and even when the valve is suffering an early stage only of what seems to be the first inflammation there is quite a number of new capillaries to be seen in it. When there is a re-infection of a valve already vascularised by a bygone inflammation fibroblastic nodules are more thickly distributed in the central parts of the valve than in cases which appear to represent an earlier phase of endocarditis. It seems, therefore, that each fresh inflammation increases the total thickening and deformity of the valve in a geometrical rather than an arithmetical progression, for each attack not only adds its quota to the sum total of fibrosis but also by increasing the blood-vessels in the valves lays it more open to further invasion.

Two important conclusions are, I believe, warranted by a consideration of the above facts with others bearing upon the subject.

1. *The type of inflammatory reaction* seen in rheumatic endocarditis is a very characteristic one. Compare it, for instance, with that seen in a valve invaded by pneumococci. In this latter the cellular reaction is exudative mainly, and the great majority of the exuded cells are polymorphonuclear leucocytes; proliferation plays quite a subordinate part. In rheumatic endocarditis there is much proliferation, the cells found being larger and more often polynuclear than in most fibroblastic reactions; the cells exuded are few in number and chiefly mononuclear in type. The two kinds of reaction are separated by a cleavage which goes to their foundations, and it seems likely that the infective agents responsible differ as essentially.

2. The micro-organisms of rheumatism (for while there is still disagreement as to the actual form of the causal agent, no one can doubt that rheumatism is a microbic disease) are carried to the valve by the coronary blood and not by that flowing through the chambers of the heart. Judging from a perusal of modern text-books, most persons still believe that organisms are deposited upon the valves, like castaways on the banks of a flood, by the blood that hurries through the heart at a high speed; that they are given a firmer "foothold" by the phagocytic action of the endothelial cells. This hypothesis is palpably improbable, but the alternative or embolic theory of endocarditis has always been met by the retort that embolism of cardiac valves cannot occur, since in the normal state they have no blood-vessels. The argument in favour of the embolic or coronary theory can therefore be arranged under three heads.

(*a*) There is evidence to show that *the inflammatory reaction of rheumatic endocarditis begins deeply and spreads to the surface.* The characteristic fibroblastic reaction may be seen sometimes in the deepest parts of a valve even when it has not been vascularised by a previous inflammation. In some of my sections areas of this kind are seen in the very centre of chordæ tendineæ. Further, the patches of mural endocarditis described in this note show a sequence of events just like those in the valves, starting with the formation of a nodule in an obviously direct connexion with the coronary blood-supply. If this is what takes place in the mural endocardium there is likely to be a similar beginning in an inflammation of the valves, since in both the later developments of the process are so closely alike. Again, we know that in about two-thirds of all cases of rheumatic endocarditis the pericardium is also inflamed, and it has been shown[3] that in practically every case the myocardium exhibits the very same type of fibroblastic inflammation. No one will suggest that these changes are produced by any other than a coronary infection, especially when we take into account the occasional discovery of fibroblastic foci in the walls of the coronary arterioles in cases of rheumatic carditis, and the very constant affection in similar cases of that part of the aorta which is supplied from the coronary arteries. Now, if in these cases every other part of the heart is infected with organisms borne into it by the coronary vessels, is it likely that the valves alone are infected at the same time and apparently by the same kind of bacteria in a different way?

Once more, if we look upon endocarditis as due to microbic invasion of the valve from the coronary circulation, we see at once one reason why the destructive types of inflammation choose valves previously damaged by rheumatism for their site. It is because rheumatic inflammation has left the valve thoroughly permeated by permanent blood-vessels, which will admit organisms to the depths of the valve in larger numbers than into a normal non-vascular valve.

(*b*) *The other, "castaway," hypothesis is wildly improbable.*—Suppose for a moment that the blood flowing through the heart were saturated with virulent micro-organisms, ready to settle on the endocardium and multiply there; would they be likely to settle on the valves, which lie right in the midst of the strongest and most direct of the intracardiac currents? Surely they would rather choose the auricular and ventricular recesses, the inlets and bays of the endocardial coast line; and we should find mural commoner than valvular endocarditis. But even allowing for the difficulty of excluding the presence of mural endocarditis by a naked-eye examination, we can be sure from experience that it is not so common as valvular inflammation, for this latter occurs in practically every case of rheumatic carditis (88 per cent., according to my own necropsy figures; 99·3 per cent., Lees and Poynton[4]).

(*c*) *The non-vascular nature of the valves does not upset the coronary theory.*—Those who believe that the valve, having no blood-vessels, cannot be invaded from its base by bacteria must explain how its tissues are nourished and also where the lymphocytes come from in rheumatic endocarditis. They must also account for the presence of micro-organisms in other non-vascular structures—for instance, the spirochæta pallida in the cornea in cases of congenital syphilis.

This is an old controversy, and some of the arguments may have done duty before, but some are new; and it has been my intention to set down in black and white a personal impression derived from independent observation and free, as far as possible, from the influence of prejudice.

Summary.—1. The reaction to rheumatic invasion of the endocardium is characterised by the formation of large fibroblasts in groups and zones, which, so far as my experience goes, are constant in rheumatic but absent from other forms of endocarditis. 2. The valvular inflammation of rheumatic carditis is set up by micro-organisms carried to the endocardium by the coronary arteries and their branches

I wish to thank my colleagues at the General Hospital, Bristol, and Dr. Reginald H. Miller, medical registrar to St. Mary's Hospital, London, for material, and also Professor I. Walker Hall for the use of the pathological laboratory, University College, Bristol.

Clifton, Bristol.

A SIMPLIFIED METHOD OF X RAY APPLICATION FOR THE CURE OF RINGWORM OF THE SCALP: KIENBÖCK'S METHOD.

BY H. G. ADAMSON, M.D. LOND., M.R.C.P. LOND.,
PHYSICIAN FOR DISEASES OF THE SKIN, ST. BARTHOLOMEW'S HOSPITAL.

DEPILATION by means of the x rays is now fully established as the most satisfactory method of treatment for ringworm of the scalp. Briefly, the treatment consists in temporarily depilating the affected area or areas, each by a *single* measured dose of x rays, and thus, mechanically, and without actually killing the fungus, eradicating it from the areas exposed. By the introduction of the pastille of Sabouraud and Noiré as a means of measurement of dosage, in trained hands, the dangers of the treatment have disappeared. One disadvantage it still has, namely, the length of time occupied by the actual exposures to the rays, and any means of shortening this period must be welcomed by all who have many such cases to treat, more especially in hospital or institution work. In a large majority of cases it is found necessary to irradiate the whole scalp. By Sabouraud and Noiré's well-known method with circular localisers from 10 to 12 exposures are necessary in order to x ray the whole scalp, and reckoning only 15 minutes for each exposure and a certain time for adjusting the localisers for each area, the time occupied in x raying the whole scalp is from three and a half to four hours. By a method which has been largely used in this country, and which I have myself employed for the past five years—namely, that of dividing the scalp into rectangular areas and irradiating each area (surrounded by a lead-foil shield) in succession—the time may be reduced to from two and a half to three hours.[1]

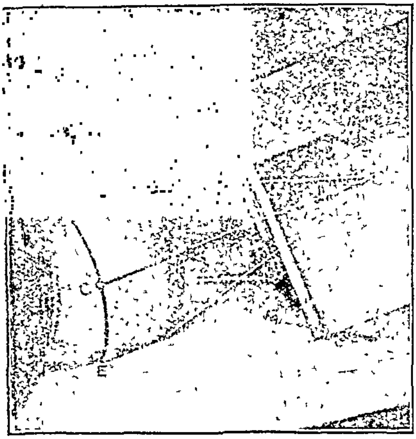
T[illegible] and L.

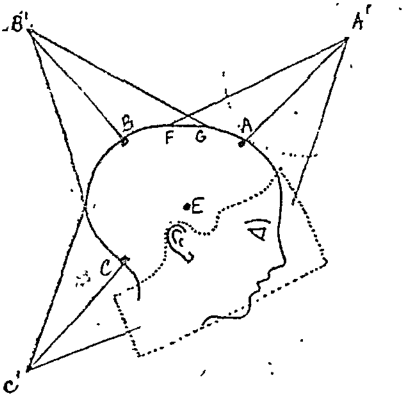
FIG. 2.



Reproduction of photograph showing [illegible] shield in position [illegible] when C is [illegible] (The pegs here shown were found to be somewhat too thick and have since been made more slender.)

By the method which I am now about to describe the number of exposures necessary to depilate the whole scalp is reduced to five, so that it is possible to irradiate the whole scalp in one and a half hours. This method was employed for the first time, I believe, by Kienböck, in Vienna, for the treatment of cases of favus and also in a few ringworm cases. Its essential features are that no cylindrical nor lead-foil localisers are used, but that adjacent x ray applications are made in such a manner that at those parts where overlapping does occur the incidence of the rays is so oblique and so much further from their source that no excessive dose is given. I have now used this five-exposure method in 75 cases with perfect results[2]; every part of the scalp has received an even radiation, and the hair has fallen completely without any sign of overlapping margins or areas with non-fallen hairs as evidence of insufficient exposure. In the earlier cases of this series the regrowth of the hair has been normal over the whole scalp, and the absence of any sign of erythema in the later cases makes it certain that they will follow the normal course, and that in due time, that is to say, in about eight weeks from its fall, the hair will begin to grow again.

FIG. 3.



(1) P[illegible] (3) [illegible] tect the ear and face when point [illegible] is x-rayed.

The details of the method as I have employed it are as follows:—1. The hair is clipped short over the whole head to facilitate operations. 2. Five points are marked on the scalp with a blue skin-pencil as follows:—

In the middle line.	Point A,	1½ to 2 inches behind the frontal margin of the hairy scalp.
	" B,	1 inch to 1½ inches above the centre of the flat area which forms the upper part of the occiput.
	" C,	just above the lower border of the scalp at the lower part of the occiput.
At the sides of the scalp.	Point D,	on the *right side just above and in front of* the ear
	" E,	on the left side just above and in front of the ear

Measured with a tape-measure the distance between any two of these five points should be exactly 5 inches. 3. The five particularly in diseases due to internal parasites, such as bilharzia, ankylostoma, and trichinæ. In trichinosis the eosinophile leucocytes may reach a percentage (of all leucocytes) of 40 to 80. Here we had one of 31 per cent., which pointed strongly towards trichinosis, as the other conditions where eosinophilia is present could be excluded. Consequently, Dr. Harris felt justified in setting in motion the sanitary machinery, with the result that Dr. L. P. Black, acting medical officer of health of St. Thomas's rural district, discovered the actual salted pork of which this man had partaken, and on Feb. 21st we examined this together and found many trichinæ among the muscle fibres. A fresh specimen made by teasing or crushing the muscle and examined under a very low power, 70–100 diameters, shows the parasites very distinctly. In the pig as a rule the capsules are not calcified and hence are not visible to the naked eye. Later I made permanent specimens by embedding in paraffin and staining with hæmatin solution and eosin, the worm taking the hæmatin and the muscle the eosin. Frozen sections are no use as the worm drops out. To get a good specimen it is important that the sections are fairly thick.

---

[1] Treatment of Ringworm of the Scalp by the X Rays, THE LANCET, June 24th, 1905, p. 1715. In the method described in this paper the scalp was divided into four areas. It was soon found, however, that it was better to divide the scalp into eight areas.

[2] In four or five cases only has there been incomplete fall of hair on certain parts of the scalp—in two cases from precautionary underdosing because a new installation was being tried, and in the rest because the wooden pegs used to keep the scalp at the proper distance were rather too thick.

On Feb. 26th I made a differential leucocyte count from a blood film taken from another patient, from the same farm, who had also eaten this pork. This was a woman under the care of Mr. C. Fenwick of Dunsford, who kindly supplied me with the film. A differential count gave the following result: polymorphs, 39 per cent.; lymphocytes, 24 per cent.; large mononuclears, 3·5 per cent.; and eosinophiles, 33·5 per cent.; a very similar result to the first case. This patient had been taken ill about the same time and had suffered from rheumatic pains and an elevated temperature, and at first had been supposed to be suffering from acute rheumatism.

In order to prevent the spread of the disease the Board of Agriculture was communicated with by Dr. Black, and an inspector was sent down to investigate the farm and its surroundings. He was fortunate in finding a dead rat on the farm. On examining its muscles it was found to be teeming with trichinæ. It may not be generally known that pigs will often kill rats, which are the normal host of the trichinæ, and probably have no objection to eating them, and hence become infected. Rats travel long distances looking for food in the country, and farms remotely situated may thus become infected. The Local Government Board has also made itself interested in this small epidemic, and in company with Mr. G. C. Hancock, one of its inspectors, I examined pork from neighbouring farms and the muscles of a rat caught for the purpose, but without results.

This outbreak of trichinosis shows the importance of bearing this disease in mind when cases occur with symptoms of pyrexia and muscular pains where the diagnosis is doubtful. If it had not suggested itself to Dr. Harris as a possibility in the case in the hospital, the epidemic, if one may so call it, would certainly have remained undiscovered. The differential blood count is also most important, and the large eosinophilia was so suggestive of trichinosis that it justified further steps being taken to find out whether the pork was infected or not.

Exeter.

CALCIUM LACTATE IN THE TREATMENT OF EPILEPSY.

BY ARTHUR R. LITTELJOHN, M.R.C.S. ENG.,
L.R.C.P. LOND.,
ASSISTANT MEDICAL OFFICER, LONDON COUNTY ASYLUM, HANWELL.

FOR some months I have been treating several epileptics with calcium lactate. The improvement in these cases since they were put on the drug is sufficiently marked to justify my recording the facts, as I have not heard of its being used before in the treatment of epilepsy. All the patients under this treatment have improved—some more so than others. They are all in an epileptic ward, where both day and night they are under constant supervision by nurses accustomed to recording epileptic seizures, so that complete reliance may be placed on the number of fits recorded. Reference to two of the more successful results obtained may perhaps persuade others to give the drug a trial.

CASE 1.—The patient was a female, married, aged 46 years; menstruation had ceased. She had had no family. There was no history of syphilis. She is said to have had a fright 17 years ago, followed by a slowly progressive right-sided hemiplegia, and two or three months later by fits. In December, 1908, her condition was as follows. She was quite lost to her surroundings, dirty in her habits, childish, incoherent, noisy, and spiteful. She showed little or no signs of right-sided paralysis, except slight swinging of the right leg whilst walking. The knee-jerks on the two sides were equal. She was having three to five fits in every 24 hours, most of them in the day-time.

The type of fit is a *petit mal* or "sensation." The attack starts by the patient screwing up her face; she then throws herself backwards and wriggles or rolls, making at the same time a bellowing noise. There is a momentary loss of consciousness but no actual convulsions and no cyanosis. The duration of the fit is less than 30 seconds.

On Dec. 19th, 1908, the patient was put on calcium lactate, 15 grains three times a day, and the following is a copy of the record kept:—

	Number of fits.		
	Day.	Night.	Total.
During the week ending Dec. 26th	34	11 =	45
" " " " Jan. 3rd	22	9 =	31
" " " " Jan. 10th	16	10 =	26
" " " " Jan. 17th	19	5 =	24
" " " " Jan. 24th	18	4 =	22
" " " " Feb. 1st	16	5 =	21
" " " " Feb. 8th	16	4 =	20
" " " " Feb. 15th	25	8 =	33
" " " " Feb. 22nd	24	10 =	34
" " " " March 1st	24	3 =	27
" " " " March 8th	21	4 =	25
" " " " March 15th ...	15	3 =	18
" " " " March 22nd ...	14	0 =	14
" " " " March 29th ...	0	0 =	0
" " " " April 5th	0	0 =	0
" " " " April 12th	0	0 =	0
" " " " April 19th	0	0 =	0
" " " " April 26th	0	0 =	0
" " " " April 27th to 30th	0	0 =	0

She has also improved mentally, and now does a little polishing in the ward.

CASE 2.—The patient was a female, aged 33 years, single; she menstruated regularly. No history was obtainable except that she had been in lunatic asylums for epileptic insanity since 1894. In January, 1909, her condition was as follows. She was lost to her surroundings, had no memory, and was very dull and confused. She was in fair bodily health. She was having from three to five fits in every 24 hours, most of them in the day-time. The number of fits had not changed appreciably during her menstrual period.

As regards the type of fit: 1. Many of her fits are "sensations." If standing up she suddenly collapses and falls to the ground; if sitting down she "jumps" and falls off her chair. Recovery is immediate. 2. Some of her fits are typical, strongly marked major epilepsy with general convulsions, loss of consciousness, cyanosis, biting of the tongue, and frequently cutting of the chin, eyebrows, or nose on the ground.

On Jan. 7th, 1909, she was put on calcium lactate, 15 grains three times a day, and the following is the record of fits since:—

	Number of fits.		
	Day.	Night.	Total.
During the week ending Jan. 14th	27	4 =	31
" " " " Jan. 21st	19	4 =	23
" " " " Jan. 28th	11	4 =	15
" " " " Feb. 4th	5	3 =	8
" " " " Feb. 11th	5	1 =	6
" " " " Feb. 18th	9	1 =	10*
" " " " Feb. 25th	7	3 =	10
" " " " March 4th	3	2 =	5
" " " " March 11th ...	2	1 =	3
" " " " March 18th ...	5	2 =	7*
" " " " March 25th ...	3	1 =	4
" " " " April 1st	1	3 =	4
" " " " April 8th	0	0 =	0
" " " " April 15th	1	1 =	2
" " " " April 22nd	0	2 =	2*
" " " " April 28th	0	3 =	3
" " " " April 29th and 30th	0	0 =	0

* Menstruating.

TWO CASES OF TRAUMATIC SEPARATION OF THE UPPER MANDIBLE.

BY WILLIAM BLIGH, M.D., B.S. LOND.

CASE 1.—On Nov. 30th, 1896, a friend and patient of mine, aged 41 years, on returning from a day's shooting was seated in a wagonette driven by a coachman. The horse bolted down a steep hill into a village and threw the coachman off the box seat. My friend, fearing for the safety of others in the village street, pluckily made an attempt by climbing over the box seat on to the horse to get command of the reins and stop the animal. He, however, fell and crashed on to the ground on his face. He was not concussed, but bled a good deal from the nose and mouth. I saw him about an hour after and found his entire upper jaw freely moveable both laterally and from before backwards, the entire mandible being apparently hinged on to the articulations of the nasal processes of the two superior maxillæ with the frontal bone. The hard palate, the nasal bones, and the nose all moved in one piece with the two superior maxillæ. There was no escape of cerebro-spinal fluid, no sign of brain injury, no hæmorrhage into either orbit, or interference with the lacrymal ducts, and very little pain or extravasation into the soft parts; in fact, my friend was so little hurt that he exhibited his new accomplishment of wagging the whole front of his face to and fro with no little pride and humour.

Treatment consisted in keeping the lower jaw firmly pressed against the upper with a plaster bandage, and gentle syringing of the nasal cavities and washing out of the mouth with an antiseptic wash. The range of movement in the mandible steadily became less and less, and within from three to four weeks the jaw was firmly fixed once more. Some not very severe neuralgia of the right infra-orbital nerve, probably produced by pressure of callus, came into evidence at the end of the second week, and lasted for about a fortnight.

CASE 2.—A woman, aged 33 years, was driving a spirited pony in a governess cart on Jan. 4th, 1909, when the animal bolted and dashed into another cart. The woman was flung out violently upon her face. I saw her within a few minutes of the occurrence and found her concussed but not deeply unconscious, in fact in a typical state of cerebral irritability. There was fairly free hæmorrhage from the nose and mouth, the left upper central incisor was found loose inside the cheek and the other left upper incisor had been knocked out but was missing; several teeth on the left side of the lower jaw were much loosened, the left lower central incisor was hanging quite loose and the right lower central incisor was turned almost completely round in its socket. The lower jaw, however, was not broken. As in Case 1, the upper mandible was quite loose in one piece and could be moved freely laterally and from before backwards hinging upon the articulations of the nasal processes of the superior maxillæ with the frontal bone, in which position crepitus could readily be detected. The soft parts of the face and the eyelids were much swollen from blood extravasation. The nose and the palate moved with the mandible. On the next day the whole face was enormously swollen, neither eye could be opened and the general aspect was that of a more or less shapeless pudding. There was no escape of cerebro-spinal fluid and no paralysis of nerves, but oozing of blood from the anterior and posterior nares continued for several days. As soon as the eyelids could be opened much subconjunctival ecchymosis could be seen but it was not wedge-shaped and evidently came from the eyelids and not from a fracture involving the anterior fossa of the skull.

The condition of moderate concussion continued for several days but no symptoms of anxiety supervened, the swelling of the face gradually lessened and the mandible steadily became more fixed, so that three weeks after the accident the jaw was nearly immoveable. On account of the state of the mouth and teeth no attempt was made to fix the fracture, the jaw was gently pressed into good position and antiseptic washes were used as in the first case.

The exact line taken by these fractures posteriorly is impossible to determine without dissection, and I do not think that a radiograph would help greatly. The malar arches in each case were intact, the separation taking place at the junctions of the malar processes of the superior maxillæ with the maxillary borders of the malar bones. In both cases the separation above took place at the articulations of the nasal processes of the superior maxillæ with the frontal bones so that the upper mandible carrying the nasal bones with it hinged upon the root of the nose just below the glabella. With these (the four main stays of the upper mandible) gone very little additional force would complete the bony loosening of the jaw, as is seen in removal of one upper jaw, where, when one superior maxilla is sawn apart from its fellow, it is only necessary to saw through the nasal process and the junction with the malar to remove the bone by rocking with lion forceps.

Judging from the second case, no treatment aimed at steadying the fracture seems necessary; nature is so kind to wounds about the face, owing to the plentiful blood supply, that the mobility of the mandible rapidly diminishes and union becomes firm without any aid from the surgeon.

Caterham Valley.

A CASE OF PULMONARY TUBERCULOSIS TERMINATING WITH ACUTE STREPTOCOCCAL MENINGITIS.

BY ERIC H. R. HARRIES, M.B., B.S. LOND.,
LATE SENIOR RESIDENT MEDICAL OFFICER, VICTORIA HOSPITAL FOR CHILDREN, CHELSEA.

A GIRL, aged 13 years, was admitted to the Victoria Hospital for Children, Chelsea, on Dec. 12th, 1907, with the following history. Six months previously she had had pneumonia, her mother not being certain whether it was "double" or confined to the left side. Since that time she had not been out of bed for longer than periods of a week or so at a time. Whenever she did get up her temperature was found to rise to 101° or 102° F. She frequently coughed up "blood and matter." She had coughed up similar material on the morning that she was brought to the hospital, and also 11 days previously. Before coughing up the sputum she would have attacks of pain in the left side sometimes accompanied by shivering. There was profuse perspiration at night. Since the attack of pneumonia the mother had noticed the girl to have a swelling in the neck and also to be losing her hair. She had menstruated regularly since the previous June, the last "period" being three weeks before admission. The only thing of note in the patient's previous history was that she had had, when seven years of age, an "open" tenotomy of the right sterno-mastoid performed for torticollis. The parents were both healthy and there was no history of tuberculosis in the family.

Physical examination.—The patient was a tall, thin girl, somewhat anæmic. The sexual features were well developed,
anc
old
of
in volume and regular. Tremors and exophthalmos were absent. The physical signs in the chest, on admission, were flattening of the percussion note over the apex of the right lung anteriorly and also over the posterior surface of almost the whole of the left lung. Over the right upper lobe the tactile vocal fremitus was distinctly increased. On auscultation, air entry into the upper lobe of the right lung was found to be diminished. Expiration was prolonged. A few crepitations could be distinguished. Beyond the flattened percussion note and a poor air entry nothing further was made out in the left lung. Examination of other systems was negative.

Subsequent course.—On Dec. 14th (two days after admission) the patient coughed up some sputum containing nummules and streaked with bright blood. At 6 P.M. the temperature was 99·4° and she complained of pain in the left side and in the region of the heart. On the 15th a smear preparation of the sputum was stained by the Ziehl-Neelsen method and counterstained with methylene blue. Tubercle bacilli were found, together with definitely capsulated diplococci morphologically resembling pneumococci. Some scattered micrococci were also seen. Unfortunately, no cultures were made to decide definitely upon the nature of the cocci. On the 18th the catamenia commenced. The general condition of the patient had improved. The enlargement of the thyroid had subsided somewhat.

five by seven inches, in which it was of a dead white colour without a single spot of purpura. It was a most remarkable appearance: the outlines were sharply defined and the skin was smooth, not raised. Here where he had put a large mustard-leaf was the only place in which the skin of the body looked natural; everywhere else it was either deeply congested or hæmorrhagic.

The patient died 15 minutes after our visit. On Feb. 24th he had taken a long bicycle ride, and on the 25th he had felt tired. On the 26th he consulted Dr. Brock who found the temperature to be 99·4° F. and the pulse 84. On the 27th the temperature was 100·8° and the patient had great pain and stiffness in the muscles and he had incessant vomiting, for which he had applied the mustard-leaf. In the evening he seemed worse and later very suffused, but there was no purpura. There was a little blood in the vomitus and in the urine. On the morning of the 28th Dr. Brock was shocked to find him with purpura, and he had had bleeding from the stomach and kidneys. The vomiting and the muscular pains suggested the possibility of malignant small-pox, but there were no papules about the forehead or wrists, and so far as he knew he had not been exposed.

The case comes in the category of the severe purpura hæmorrhagica of unknown origin. The feature of special interest is the absence of purpura in the limited area of skin upon which a blister had been applied. The stimulation of the mustard had altered in some way the capillary walls, rendering the cells insusceptible to the endotheliolysis, which (as in the snake-venom experiments) we may suppose to be the primary change, under the influence of some unknown poison.

Oxford.

CASE OF CEREBRAL HÆMORRHAGE FOLLOWED BY HYPERPYREXIA AND DEATH.

BY VINCENT P. NORMAN, L.M.S.S.A. LOND.

THE following case may prove of some interest, being, as it was, followed by hyperpyrexia—a clinical fact not often recorded if we judge from a perusal of literature bearing on the subject. Dr. William Osler in his text-book on medicine mentions that in basal hæmorrhage "the temperature may be high," and other authorities, while making the same statement, do not say as to how high the temperature has been known to rise. Hence my reason and apology for recording the following case.

In the present instance the patient, aged 52 years, was of powerful build and plethoric appearance. The history obtained was that up till the age of 36 years he had been a rigid teetotaler, when he gave way to alcohol and had been drinking steadily ever since until about six months before his death. During the last 15 months he had had in all three "strokes," very mild in character and all of which appear to have cleared up completely; his fourth and last attack occurred on July 28th, 1908, leaving behind it left-sided hemiplegia and incontinence of both urine and fæces. When the patient came under my observation on July 31st I found his left arm and leg completely paralysed. He was conscious but appeared to be dazed and answered indistinctly and in monosyllables when spoken to and only after the question had been repeated several times. His temperature on July 31st at 2 P.M. was 100·4° F., the pulse being 78, and the respirations 24 per minute. On the evening of the same day I was asked to go and see him again as he had taken a turn for the worse. On feeling his skin I was at once struck by the sensation of extreme heat imparted to the hand. The pulse was of low tension and 130 beats to the minute; the respiration had risen to 36, and the temperature taken in the axilla was 108·4°. As the patient was in evident grave danger I decided on trying the effect of cold as a means of reducing the temperature. It was found impossible to move the patient out of bed into an iced bath as he was fully 18 stones in weight, so I got a mackintosh under him and wrapping him in a sheet sprayed it all over with iced water, lumps of ice being left between the sheet and the patient's body. At the same time he was fanned vigorously so as to cause rapid evaporation. At the end of one hour the temperature had fallen to 104°, and the pulse was still rapid and perceptibly weaker. The cold spraying was continued and a hypodermic injection of one-thirtieth of a grain of strychnine hydrochloride was given; the pulse improved somewhat. An hour later the thermometer registered 101·2° in the axilla, the pulse was 100, and the respirations were 34 per minute. The application of the cold water was now discontinued, the patient dried rapidly and was covered with a light dry sheet, another hypodermic injection of strychnine being given. I now proceeded to examine the lungs for possible pneumonia but could detect no signs of such a condition; the cardiac sounds were weak, a blowing systolic murmur being audible in the mitral area. The temperature was now taken at intervals of an hour and showed a steady rise, till by midday on August 1st it had risen to 107·6°. The application of cold was resorted to again with the result that by 2.30 P.M. the temperature had fallen to 102·4°; it, however, soon after began to rise again, and when I saw the patient at midnight he was very weak and obviously sinking fast. The axillary temperature was 108·6°, the rectal 109°, the pulse was scarcely perceptible at the wrist and so rapid that it could not be counted, and the respirations were Cheyne-Stokes in character. It was clear that nothing more could be done. However, I continued the sponging with iced water and packed the patient around with ice and gave him one-twentieth of a grain of strychnine hypodermically, but he in no way responded to the treatment and died at 1.35 A.M. on August 2nd, the axillary temperature just before death registering 109°.

In the above case a point of some interest was the rapid rise of the temperature and its equally rapid fall under the influence of cold, the latter causing a drop in the first instance of something like 7° in two hours and again of 5°, although just before death supervened the temperature remained unaffected by the treatment. Unfortunately the exact seat of hæmorrhage could not be accurately localised, post-mortem examination being unobtainable.

Stoke Newington.

NOTES ON TWO CASES IN WHICH THE APPENDIX WAS PRESENT IN A HERNIAL SAC ON THE LEFT SIDE.

BY OWEN RICHARDS, M.CH. OXON., F.R.C.S. ENG.,

SURGEON TO KASR-EL-AINY HOSPITAL, CAIRO.

IN THE LANCET of Jan. 9th, 1909, p. 100, Dr. A. D. Griffith describes a case in which he found the appendix in a left inguinal hernia in a woman, and gives references to the literature showing that this condition is extremely rare. For this reason it may be worth while to record two similar cases, not otherwise remarkable, which I have recently seen.

The first case was one of left-sided inguinal hernia in a man, aged 45 years, who was operated upon in April, 1908. Symptoms of strangulation had existed for three days before admission to hospital. A big tense sac occupied the scrotum and on clearing and opening it I found the cæcum, the appendix, and parts of the ileum and ascending colon. The colon had a distinct mesentery. The whole was returned, the opening was closed in the usual way, and the patient made a good recovery.

In the second case the patient, a man, aged 40 years, was operated upon in September last by my assistant surgeon, Dr. Aly Bey Ibrahim. There was a large irreducible inguinal hernia which filled the left side of the scrotum and contained the cæcum, the appendix, parts of the ileum, the ascending and transverse colons, and a quantity of omentum. A good deal of omentum was removed and the operation was completed in the usual way. The patient went home healed a fortnight later.

Neither case showed any obvious abnormality, and in both there was noted to be a distinct mesentery. Both patients were Egyptians.

In three cases in which I have recently found the cæcum and appendix in a hernia on the right side two were instances of hernia by *glissade*. In the third case, in which the hernia was strangulated, the colon possessed a mesentery which was attached higher up the abdomen. In one of these cases the distended cæcum lying in the scrotum had been previously diagnosed elsewhere as a hydrocele and tapped, with disappointing results. Fortunately, it was adherent and no harm resulted.

Kasr-el-Ainy Hospital, Cairo.

ROYAL SOCIETY OF MEDICINE

SURGICAL SECTION

Jejunal and Gastro jejunal Ulcer following Gastro jejunostomy —Auto inoculation and Reinfection of Syphilis

A MEETING of this section was held on May 11th, Mr J WARRINGTON HAWARD being in the chair

Mr HERBERT J PATERSON read a paper[1] on Jejunal and Gastro jejunal Ulcer following Gastro jejunostomy, with notes of two cases in one of which gastric analyses were made before and after operation for jejunal ulcer, with an abstract of 61 further cases and observations thereon He said that notwithstanding all that had been written in recent years on the subject of gastro jejunostomy there remained at least one problem in connexion therewith in need of further investigation and elucidation The fear of the possible occurrence of a jejunal ulcer still casts a shadow, faint it was true, over the otherwise admirable results which follow this operation when performed in appropriate cases It was of the utmost importance that all instances of this condition should be published, in order that they might have all the available material from which to draw conclusions as to the etiology of this condition, as to the best methods of preventing it and of treatment should it occur The notes of the following case which had been under his care were of interest, as it was, so far as he could gather, the first case in which an attempt had been made to obtain an accurate analysis of the gastric contents, and of the fluid escaping from a jejunal fistula before and after operation for ulcer of the jejunum The case was one of anterior gastro jejunostomy for pyloric stenosis, perforation of a jejunal ulcer five years later, resection of affected portion of jejunum, and anterior gastro jejunostomy ' en Y " The patient was a married woman, aged 47 years who was admitted into the London Temperance Hospital on August 21st, 1902, under the care of Dr W Soltau Fenwick, suffering from pain after food vomiting, and loss of flesh The patient stated that she had always been healthy until two years previously, when she began to suffer from pain after food which gradually increased in severity, and she had lost three stones in weight For one year she had suffered from vomiting usually two or three times weekly, large quantities of partially digested food being brought up On admission the patient was much wasted and weak, and weighed 6 stones 5 pounds instead of 9½ stones The stomach was markedly dilated, the lower border reaching a hand s breadth below the umbilicus There were constant visible peristalsis and a marked succussion splash At the level of the umbilicus close to the outer border of the right rectus muscle there was a hard moveable lump rather larger than a walnut There was a marked free hydrochloric acid reaction in the stomach contents after a test breakfast, and also in the contents of the fasting stomach Lactic acid was not present Dr Fenwick thought that the dilatation of the stomach was due to cicatricial stenosis of the pylorus and asked Mr Paterson to see the patient with a view to operation The patient declined to have anything done and left the hospital on August 27th On Sept 6th the patient returned, looking a good deal worse and stating that she had been vomiting constantly She had lost over four pounds in weight and now readily consented to operation On the 8th he opened the abdomen The stomach was large and much hypertrophied In the region of the pylorus was a densely hard mass of about the size of a walnut and situated mainly in the posterior wall There were no adhesions and the lump was freely moveable Anterior gastro jejunostomy was performed by means of a single layer of Halsted sutures, the opening The pylorus was explored complete, stricture was f uninterrupted recovery and left the hospital three weeks later This was one of his earlier gastro jejunostomies, and he must admit that at the operation he thought the pyloric lump to be malignant, and he proposed to reopen the abdomen, remove a portion of the lump for microscopical examination, and if, as he anticipated would be the case, the lump were malignant perform partial gastrectomy Clearly he was wrong in his opinion, but fortunately the patient felt so well that she declined to have any further operation Two years later, in August, 1904 he saw the patient again She then told him that she had never had a day s illness or pain of any kind and that she was able to eat ordinary food She looked a different being and weighed 9 stones 4 pounds a gain in weight of over 3 stones The abdominal wound was soundly healed and no trace of the pyloric lump could be felt On August 13th, 1907, the patient was readmitted into the hospital She stated that ever since the operation she had enjoyed excellent health Two years before readmission she began to have some pain after food, but the pain was not severe and did not cause her much inconvenience During the previous nine months the pain had increased, nevertheless she continued to eat all kinds of food cheese, tinned foods, &c For three months the patient had noticed a lump forming in the abdominal wall above the umbilicus On August 13th the skin over the lump gave way and much yellowish fluid escaped She was seen by Dr Percy Edmunds, who at once sent her into the hospital The patient looked exceedingly well and had become very stout and weighed over 12 stones Midway between the umbilicus and the ensiform cartilage, immediately to the left of the middle line, was an aperture in the abdominal wall with shelving indurated edges from which escaped a turbid yellowish fluid apparently containing bile Around the aperture there was considerable induration and the skin for some distance around was much thickened A diagnosis of perforated jejunal ulcer was made As the patient was so well nourished it was thought advisable to postpone operation with a view of getting the skin into a more healthy condition and also of reducing the gastric acidity and rendering the intestinal contents sterile by keeping her on an exclusively milk diet This period of waiting was utilised to make a series of examinations of the gastric contents and of the fluid escaping from the fistula The examinations were as follows —August 20th, test breakfast One hour later the stomach contents drawn off 110 cubic centimetres Total acidity, 85, total chlorides, 0 433, free HCl, 0 072, protein HCl, 0 208, mineral HCl, 0 153 During the digestion of the test breakfast and for half an hour later the fluid escaping from the fistula was collected and analysed with the following result Total chlorides 0 405, free HCl, 0 044, protein HCl 0 175, mineral HCl 0 186 On August 27th, after the patient had been on a milk diet for a week, the analysis of the gastric contents was as follows Total acidity, 80, Gmelin s reaction absent total chlorides 0 361, free HCl, 0 018, protein HCl, 0 187, mineral HCl, 0 146 At the same time 60 cubic centimetres of fluid were collected from the fistula Gmelin s reaction present, total chlorides, 0 372, free HCl 0 004, protein HCl, 0 092, mineral HCl 0 276 Sept 3rd 70 cubic centimetres of fluid were collected from fistula Total acidity, 60 total chlorides 0 401, free HCl, 0 004 protein HCl 0 109 mineral HCl, 0 292 At the operation on Sept 5th 1907, an oval incision was made through the skin around the fistula and carried downwards through the fasciæ and muscles The peritoneum was cut through in the middle line well below the fistula and a finger was introduced into the peritoneal cavity The jejunum was found adherent to the abdominal wall for some distance on either side of the fistula The fistula was plugged with gauze and the peritoneum carefully cut through clear of the area adherent to the jejunum It was then apparent that the fistula led directly into the efferent limb of the jejunum one inch below the site of the anastomosis with the stomach Six inches of jejunum, including the perforated ulcer and the skin attached to it, were resected After separating the jejunum from the stomach the opening in the stomach measured one inch by half an inch This opening was enlarged and the distal end of the jejunum was implanted into it and the proximal end of the jejunum was implanted into the side of the jejunum four inches below the anastomosis with the stomach Both anastomoses were performed by means of two continuous pressure of a fluid flowing through a tube could arise from contraction of the tube was altogether ignored by Crile, and some of his supporters had even said that it was not so, that the pressure was as high as, some said much higher than, that in the narrow part of the tube, forgetting that it was a difference of pressure that made a fluid flow. The fact that the blood was in an enclosed space must not be forgotten. The effect of this was that although contraction of a vessel tended to lower the blood pressure within it because the fluid flowed, yet the blood must collect somewhere, and naturally it was found in the weakest part of the vascular system, i.e., in the large veins. This accounted for the raised pressure in them which did not exist in the pithed animals and which was not accounted for by Crile's theory. Roy and Adami showed that peripheral irritation not only contracted the arteries but also increased the force of the ventricular contractions, and Eugene Boise, of Grand Rapids, Michigan, had pointed out that as shock increased the heart action became more limited until its dilatations were so small that it could not take up and propel sufficient blood into the aorta, the pressure then fell and the blood accumulated in the veins. Crile's explanation that the heart could not get sufficient blood because of the low pressure in the veins was considered unsatisfactory and irreconcilable with his previous statement that the veins were engorged. Whether the vessels were dilated or contracted in shock changes of calibre certainly occurred and the conditions necessarily returned to the normal during recovery. Hence it was necessary to divide the treatment of shock into two stages, first to prevent change and later to promote a return to the normal. Crile taught that the vessels dilated as shock progressed and should be filled with fluid and contracted if possible. Mr. Malcolm held that the vessels contract in shock, that the fluids were squeezed out of them and removed from the body as sweat. Hence vaso-dilators and sedatives should be given as shock developed, and the administration of fluids was necessary in the stage of recovery. In support of this last view Crile was quoted to the effect that as shock deepened the quantity of fluid that could be taken into the veins became progressively smaller, and that in deepest shock fluid so injected escaped into the tissues almost immediately. Mummery had confirmed these views, which did not seem to support his contention above mentioned that the volume of the blood naturally increased in shock. On the other hand, in the days when fluids were rigidly withheld after operations patients often remained in a state of profound shock for many hours. Now it was known that a free administration of fluid was all that was necessary to insure prompt recovery in an uncomplicated case. The evidence seemed complete that in shock fluids were removed from the vessels and from the body and had to be replaced before recovery was possible. Hence endeavours to force blood into the veins in the stage of developing shock were considered useless and dangerous. When the vessels relaxed the danger of collapse was great. Vaso-dilators were then unnecessary and increased the danger unless fluid was also supplied. Hence it was desirable to introduce fluid in anticipation of the necessity for it, and the dangers of venous injection could be avoided by introducing the fluid into subcutaneous tissue, the rectum, or the peritoneal cavity. The employment of vaso-constrictors when the arteries were empty and would not dilate or would not remain dilated was considered irrational, whilst alcohol was considered useful and undoubtedly improved the pulse in that stage. The action of strychnine had been condemned by Crile because when convulsions were prevented by curare in repeated doses it produced a rise of blood pressure followed by a fall until the condition of low pressure in shock was brought about. Here again the possibility that strychnine might stimulate an intense arterial contraction which reduced blood pressure by narrowing the vessels was altogether ignored and the conclusion was arrived at that strychnine paralysed the vaso-motor centres. The improvements of the methods of administering anæsthetics, the disuse of irritating antiseptics, the use of the Trendelenburg position, and the anticipation of septic and inflammatory troubles by improved diagnosis and prompt treatment were important measures for preventing shock. The greatest danger arose in septic cases in which the vascular changes of shock were already partially produced. In such cases fluid was required as a food and never less than during an operation. It should therefore be given subcutaneously during or even before a surgical procedure was commenced to replace fluid lost and to fill up vessels whenever they tended to relax. The treatment of septic peritonitis by continuous rectal injections was explained in a similar way. In such cases there was always a free discharge from the peritoneum for from 12 to 30 hours after the operation if recovery ensued. This drained the body of fluid, and if the loss was not made good the patient could not recover but died partly from shock and partly from sepsis.

---

[1] The expenses of the investigations referred to in the course of the paper were defrayed by a grant from the Science Committee of the British Medical Association

Mr. C. R. B. Keetley said that shock was less seen now because of the care taken to prevent hæmorrhage, to keep the patient warm, and because of the substitution of ether for chloroform. He deprecated the extent to which strychnine was used in the operating theatres.

Mr. A. Pearce Gould said there were three elements of primary importance in the treatment of shock: external warmth, rest, and a small dose of morphine. He agreed that the hypodermic injection of strychnine was useless.

Dr. Alexander Morison pointed out that shock passed off when the power of the heart's action returned; the application of warmth or the inhalation of amyl nitrite quickened the action of the heart.

Mr. V. Warren Low spoke of intravenous saline injection in very severe degrees of shock.

Mr. Lockwood raised the question of the definition of shock and described an instance in which the administration of oxygen produced an amelioration of the condition after other remedies had failed. He had seen gangrene follow injections of brandy and ether into the tissues.

Mr. Malcolm said his remarks referred to conditions of shock produced gradually in a prolonged operation. He thought shock was due to the contraction of the vessels and that it killed slowly; syncope occurred when the vessels were relaxed when there was not enough blood to fill them. In regard to the injection of fluid into a vein he said that Crile's view was that if saline solutions were injected into a vein in conditions of shock the fluid merely passed into the tissues.

Mr. T. H. Kellock read a paper on Associated Disease of the Vermiform Appendix and Fallopian Tubes, which was discussed by Mr. Charles Ryall, Mr. Malcolm, Mr. William Rose, and Mr. Lockwood.

OPHTHALMOLOGICAL SOCIETY.

Tubercle of the Choroid.—Spring Catarrh.—Atropine and Refraction Work.—Exhibition of Instrument and Cases.

A meeting of this society was held on May 6th, Mr. R. Marcus Gunn, the President, being in the chair.

Dr. G. Carpenter read a paper entitled, "'A Clinical Contribution to the Study of Tubercle of the Choroid." The first patient, under Dr. J. Porter Parkinson, aged seven years, had been getting thinner. He was admitted to hospital with physical signs at the right apex, front and back. There was a history of abdominal pain, but no cause for it could be discovered by palpation. The child then became drowsy and comatose, with great wasting. There were six choroidal tubercles and flecks of retinal pigment were scattered about them. Three of the tubercles were crossed by retinal vessels. The second patient, a girl, aged two years, had been ailing six weeks and had had sickness and headache five days. When admitted she was suffering from meningitis, and died on the sixth day. The right fundus was normal and no tubercles or optic neuritis could be seen, but on the left side there was slight papillitis. Close to the optic papilla was a tubercle of considerable size, and several blood-vessels crossed its face. The retinal arteries were small; nothing was noticed about the veins. The surface vessels of the brain were congested. The diagnosis was verified at the necropsy. The next case was that of a boy, aged 17 months, who had much the same physical signs. He had meningitis, which was later corroborated by lumbar puncture. Another case was that of a boy, aged two years, who had had a bad cough five weeks and when admitted had consolidation at both apices. There was a small amount of papillitis in both eyes. He died 12 days after admission, no changes having occurred in the fundus in the meantime. Several other cases of the kind were recorded, and Dr. Carpenter then proceeded to discuss the readiness which had been shown to attribute such appearances to syphilis, whatever evidence to the contrary might have existed. He urged early and systematic ophthalmological examinations, which would often render unnecessary spinal punctures, or injections of substances to induce reactions.—The paper was discussed by the PRESIDENT and by Dr. FREDERICK E. BATTEN, the latter gentleman commenting on the comparative infrequency of tubercle of the choroid in tuberculous children, and stating that he was under the impression that spinal puncture afforded a more certain indication than ophthalmoscopic observation.—Dr. CARPENTER replied.

Mr. J. MACKENZIE DAVIDSON and Mr. ARNOLD LAWSON communicated a paper entitled, "A Case of Spring Catarrh Treated and Cured by Radium." The patient was a boy, aged 12 years, who suffered from chronic photophobia, lacrymation, and slight conjunctival discharge which had persisted for nearly a year; but no exciting cause could be discovered. Both tarsi were covered with dense hard excrescences, closely aggregated, and separated by deep narrow fissures. The retrotarsal tissue was swollen and hypertrophied and the viscid discharge was spread over the conjunctival surface. The disease was confirmed by examination of the discharge. The irritability was chiefly marked in the morning. He was ordered complete cessation from close work and dark glasses for out of doors. Yellow mercuric oxide was used, but no benefit resulted, and it caused too much pain. A week later he had cupric sulphate drops of a strength of one grain to the ounce. In August the boy went to the seaside against Mr. Lawson's advice and got worse there. Bicarbonate of soda and hydrocyanic acid gave relief and weak copper sulphate drops were used from time to time still. He then consulted with Mr. Mackenzie Davidson as to the possibility of treating the case with radium. It was carried out for a year, during which period each eye was treated eight times. No pain or other immediate effect was produced but the granulations gradually subsided. After the eighth application he was quite cured, but the interval before reading the communication was to make quite sure there had been no recurrence for a good [illegible] were used for 15 minutes [illegible] Mr. Lawson thought that [illegible]ose of radium was better [illegible] a weaker quantity.—Mr. [illegible] the case, pointing out the importance of being sure that the strength of radium used was what it was said to be, as he had found serious discrepancies. It was also very important to cut off those radium emanations which were not needed in the cure.

Mr. R. R. CRUISE read a paper on the Abuse of Atropine in Refraction Work. The paper was based on the examination of 140 eyes under 16 years of age. He concluded that, on the whole, homatropine and cocaine were quite equal if not superior to atropine, though in most cases the result after the two mydriatics was identical.—The paper was discussed by Mr. S. STEPHENSON, Mr. N. BISHOP HARMAN, and Mr. C. DEVEREUX MARSHALL, the latter of whom alluded to Mr. W. Lang's investigations on the matter; and Mr. ERNEST CLARKE said it would have been useful to learn what the astigmatism was in the cases.

Mr. M. S. MAYOU read a communication on the Disappearance of the Iris from the Pupillary Area following Injury.

Major R. H. ELLIOT, I.M.S., exhibited Instruments: (a) An Evisc[illegible] use in the opera[illegible]) an Elevator for [illegible]

Mr. STEPHENSON *showed a case of Congenital Anterior Staphyloma in a baby, who also had absence of patellæ,* [illegible]es. [illegible] pear- [illegible]

Mr. E. TREACHER COLLINS showed a case of Nodular Leprosy affecting the Eyes; also a case of Progressive Bilateral Ptosis.

UNITED SERVICES MEDICAL SOCIETY.

Physical Training and the Medical Profession.

A MEETING of this society was held on April 14th, Colonel D. WARDROP, A.M.S., being in the chair.

Surgeon KENELM DIGBY BELL, R.N., read a paper on Physical Training and the Medical Profession. After lamenting the national tendency to "specialise" in modern sports and to neglect the well coördinated training of the body and the mind the speaker said: "It must be our duty to ensure that some sound method of physical education is universally adopted to encourage the building up of a healthy body to keep in touch with the rapid growth of mental education. The true object of physical training should be to increase the strength, agility, and power of endurance of our boys and men. By 'strength' I do not mean large muscular development (as is so commonly understood) but an even balance of work between every organ and function of our body, striving to produce an all-round man. We must endeavour to build up the feeble to a good medium of health and strength; we should strive to diminish annually the number of social wasters which the modern conditions of life tend to increase. Discretion and experience warn us of the error of acrobatic sights which pervert public spirit. The results of physical training lose their interest if instead of benefiting the mass they serve to form certain athletes to satisfy the vain curiosity of the crowd. In the Services the need for some daily routine of exercise to keep the men fit and ready for any duty they may be called upon to do, without strain to their individual economy, has been recognised for some years now and the schools of physical training at Portsmouth and Aldershot turn out annually officers and men [illegible] sioners of the Admiralty, as [illegible] Training School at Portsmou[illegible] still employed, and also had [illegible] course of instruction at the [illegible] Stockholm last year. The fact that I was in attendance as honorary medical officer at the Olympic games in London last July gave me a further advantage, as I seized every opportunity of studying the types of physique of the various nations competing and the different systems of gymnastics performed by the teams at the Stadium. My constant endeavour has been to study the various exercises from the practical as well as the theoretical point of view in order to learn what is being taught and to feel the effect of the exercises on myself personally. I am fully convinced that the best method for conducting the physical training of numbers of boys and men is on the lines of the Swedish system of gymnastics." Surgeon Bell then proceeded to describe the general principles of that part of the system employed in the navy and army schools—namely, educational gymnastics—of which the three fundamental characteristics were: (1) the nature and intention of the exercises; (2) the progression of the exercises; and (3) the definite arrangement of the exercises in the daily lesson. Every exercise had a special physical effect embodied in it, which was chiefly dependent *on the changes, produced* in accordance with the laws of physiology, in the organs of locomotion taking part in the movement and in those parts of the nervous system which were called into play by it and each exercise was practised solely to produce that effect. There were some 900 to 1000 distinct exercises *in the system and the combination* of those was almost infinite, so that there was large scope for variety and individuality. The progression of the exercises had been so carefully thought out and described that the whole training could be carried out by persons of any age or special requirements without overstrain or damage. The exercises should be graduated and the so-called position of attention should be gradually reached by careful training and [illegible] found to [illegible] The [illegible] be [illegible] ovided [illegible] for the all-round development of every organ and function of the body. A certain definite order was employed based on [illegible]t several [illegible] her and [illegible] muscles [illegible] had been concentrically contracted for any period of time they were at once extended by the exercises which immediately followed and in this way their full capacity of action was assured which kept them supple and expansile instead of allowing them to remain shortened and fixed as was often the case when their contra[illegible] Great attention was paid to the [illegible] resilient chest in the youn[illegible] life, so that the breathing might be free at all times and the fixed condition of the chest—so common from older forms of gymnastics—might be prevented. No exercise was applied for developing big and fixed muscles, so the overstrain attending such attempt was avoided. The qualities aimed at in this direction were suppleness, coördination, smart reaction, and agility. A great and obvious advantage was embodied in the fact that the exercises could be performed in the open air when the atmospheric condition of the English climate permitted it. This system of gymnastics had been employed for some years now in nearly every nation in Europe. Partly owing, no doubt, to the fact that England has offered a free dumping ground for numbers of so-called professional experts to practise their various methods of physical culture, and to advertise these methods as treatment for the cure of all sorts of diseases, the mention of physical training had come to have an echo of charlatanism attached to it. Too little interest was taken in the subject by the majority of the medical profession. Surely a cause with such grand principles as physical training on sound lines offered had need of the guidance and interest of medical men to keep it on sound lines and to ward off any taint of quackery from accompanying it. Setting aside the great benefits to be derived in the future by endeavouring to build up the physique of the race to-day, a man who kept himself fit or who was kept fit by regular exercise, had an active and clean mind, was temperate in his habits, and took a pride in himself and his surroundings. Surgeon Bell concluded his remarks with an appeal to medical men to study and spread the knowledge of this important branch of science.

The discussion which followed had reference to the position of attention, the effects of urban life on development, thebenefits of physical training in schools and of universal military training, specialising, the effect of physical training on mental capacity, the defects of the Swedish system, and the contamination of systems by quackery.—Lieutenant-Colonel M. W. H. RUSSELL, R.A.M.C., Dr. W. P. HERRINGHAM, Dr. GILMOUR, Lieutenant-Colonel C. H. MELVILLE, R.A.M.C., Major C MOORE, Dr. M. S. PEMBREY, Lieutenant-Colonel H. E. DEANE, R.A.M.C., Lieutenant COOKE, R.N., Lieutenant-Colonel A. B. COTTELL, R.A.M.C., and Fleet-Surgeon G. T. COLLINGWOOD, R.N., were among the speakers.

In his reply, Surgeon BELL maintained that although the ideal state of affairs would be for each person to train himself physically on his own individual lines, this was impossible in the Services to-day, and a system was absolutely necessary for the physical training of numbers of boys and young men. On the subject of specialising, the speaker explained that he would be the last person to do otherwise than encourage sports as long as there was an element of all-round training embodied in them, but that he could not get away from the fact that we were as a nation carrying competition too far. He advocated general training on rational lines without undue enthusiasm in competition having for its object the development of an all-round man.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.—The Histology of Accessory Sinus Suppuration.

A MEETING of this society was held on May 5th, Dr. JAMES RITCHIE, the President, being in the chair.

At the private business M. Metchnikoff was elected an honorary member, and Professor C. F. Martin of McGill University, Montreal, and Professor L. F. Barker of the Johns Hopkins University, Baltimore, were elected corresponding members.

Dr. BYROM BRAMWELL exhibited: 1. A case of Scleroderma of the Hands and Lower Parts of the Forearms in a stonemason. The characteristic hide-bound condition of the skin was evident. The integuments were so tightly stretched that movements were impeded and when the hands were cold they felt like those of a frozen corpse. He had seen the same condition in four or five other stonemasons and stated that it was due to holding the cold chisel in cold weather. The patient had been treated by injecting fibrolysin and with improvement so that the skin on the back of the hand could be pinched up and the hands felt less cold. Although the injected material was absolutely sterile he had observed a rise of temperature to 104° F. and with rigor after each injection, though in a case of disseminated sclerosis there was no rise during a period of many injections, but hyperpyrexia followed the subsequent injections. 2. A case of Functional Nervous Disease treated by isolation, faradism, and the hypodermic injection of water. The case occurred in a girl, aged 12 years. Some years previously she had been bitten on the leg by a dog, and every night at 7.30 or 8 P.M. she had a recurrence of the pain, this corresponding to the hour at which the dog had bitten her, and she then assumed the same position as when she was bitten The pain was so severe that beads of perspiration came out on her forehead. The treatment had effected a complete cure.

Dr. NORMAN WALKER showed: 1. A case of Acanthosis Nigricans. This was a rare condition, only some 30 cases having been recorded since the first in 1889. It consisted in a peculiar change and proliferation in the layer of prickle cells of the skin, leading to warty growths and a plush-like condition with pigmentation of the skin. The patient was a washerwoman and the disease had lasted eight years. The disease was most frequently associated with malignant disease, but in one or two cases in younger persons this was not seen. It was not due to disease of the suprarenal glands and treatment did not seem to have much effect. 2. A case of Pityriasis Rubra Pilaris. This was a disease peculiarly difficult to influence, but this case had been greatly benefited by hypodermic injections of soamin and the patient increased one stone in weight. Dr. Walker had always thought that lichen planus had a relation to syphilis and hence the use of soamin. 3. A case of Lichen Scrofulosorum treated with cod liver oil externally and given internally. 4. A case of Lupus treated by the local application of tuberculin. In experimenting with Pirquet's test he had vaccinated over lupus patches and so produced very considerable reaction. A 5 per cent. Koch's old tuberculin in vaseline was employed and in one or two days the part became very painful and the reaction continued for a considerable time. It caused, however, the disappearance of a very great deal of disease and had dissipated the fibrous tissue, so allowing of a free movement of the elbow and right arm, which were affected in this patient. A 10 per cent. solution of old tuberculin in saline solution was tried on two patches, with the result that the lupus nodules were eaten out as by salicylic acid. In another case of lupus on the face and arm there was very violent local reaction and a very disagreeable smell was produced, but after cessation of reaction the absorption of nodules went on most satisfactorily. Very little difference was observed in the reaction between bovine and human tubercle in Pirquet's test.

Professor F. M. CAIRD showed: 1. A man, aged 39 years, after ligature of the right subclavian for Axillary Aneurysm. A large pulsating mass had existed for two years with pain in the elbow and shoulder and loss of power in the hand. As the condition was progressing the subclavian was ligatured it its third portion. The case had progressed very satisfactorily and there was no return of pulsation in the axillary or radial arteries. It would be necessary for him to take care of his hand for some time. 2. A case after operation for Internal Strangulation. The diagnosis was made of appendicitis with perforation, but on operation the intestines were found in normal condition, but there was a constriction of the jejunum by a loose strand of fibrous tissue which contained a well-marked artery. 3. An Elephantiasis-like Condition of the Left Leg Produced by Bier's Method of Passive Congestion. This treatment had been advised for tuberculous disease of the knee-joint, but the patient had kept on the bandage for three days and three nights applied at the middle of the thigh. The leg was enormously increased in bulk and pitted on pressure. A mass of lymphatic glands could be felt in the groin passing up into the saphenous opening.

Mr. HAROLD J. STILES showed: 1. A woman after Pylorectomy for Chronic Ulcer of the Stomach. She had suffered from chronic dyspepsia for many years, with continuous pain, but without bleeding or any special symptoms. A small, indurated, but moveable swelling was present in the pyloric region. The diagnosis was made of carcinoma of the pylorus, but neither at the operation nor after the pyloric portion had been removed and slit up was it possible to say whether the ulcer was simple or malignant The microscope showed later that the ulcer had become carcinomatous A gastro enterostomy was performed and now, five weeks later, the patient remained well For 20 years she had complained of gastric symptoms, great acidity, and hunger pain relieved by eating a crust of bread It might be advisable to remove very chronic ulcers 2 A Specimen of Extensive Tuberculous *Disease of the Glands on Both Sides of the Neck* Removed by Operation

Mr J W STRUTHERS showed a child, aged 17 months, after operation for head injury An hour after falling out of a go cart violent clonic spasms of the entire right side developed and continued As the child was obviously dying a flap of scalp and bone was turned down on the left side of the skull and large amounts of fluid escaped on opening the dura The convulsions at once ceased and have not returned

Dr J S FRASER read a paper on the Histology of Accessory Sinus Suppuration He said that the accessory sinuses of the nose were developed by the absorption of the cancellous bone in the superior maxillary, sphenoid, ethmoid, and frontal bones respectively, and the invasion of the spaces so formed by hollow ends of mucous membrane from the nasal cavities It was important to note that the accessory sinuses were lined by mucous membrane continuous through the ostia with that of the nasal cavities, it seemed probable that the mucosa of the sinuses would take part in any changes which the nasal mucous membrane might undergo The communication was meant to show that the changes in the mucous membrane of the accessory sinuses were analogous to those which occurred in the nose in catarrhal and suppurative conditions and in the middle ear cleft in catarrhal and suppurative otitis media, and that the condition of "catarrh' passed insensibly into the condition called "suppuration' [illegible] the accessory sinuses [illegible] e of the cavities they [illegible] very badly situated [illegible] accessory sinuses was described and was compared with that present in acute and chronic inflammation In one case of *acute sinus suppuration* the prominent microscopical feature was the extensive hæmorrhage in the submucous tissue and the engorgement of the vessels Small cell infiltration *was not so marked as in chronic cases and the* œdema was slight The superficial epithelium was almost normal In *chronic inflammation* a thick layer of catarrhal or purulent secretion was present It was remarkable how often the superficial layer appeared to be normal although there were marked changes in the submucous tissue The ciliated layer was often absent in parts and leucocytes could be seen making their way between the epithelial cells to the surface, there to mix with the mucous secretion to form the muco purulent or purulent secretion Both mono and polymorpho nuclear cells might be seen and occasionally eosinophiles in the same situations As the quantity of mucus poured out in the sinuses was scanty, and *the leucocyte exudation relatively* great, the discharge was more definitely purulent in contrast to the muco purulent discharge from the nose In three out of nine antral cases examined the superficial cells were more of the squamous than of *the cylindrical type*, and in none of his specimens did the loss of superficial tissue extend deeper than [illegible] was not met with [illegible] it membrane was, [illegible] of chronic [illegible] usually much in- [illegible] conditions, due [illegible] r engorgement and small cell infiltration This led to a widening of the delicate connective tissue network, so that large spaces were formed filled with serum The process was similar to the formation of nasal polypi in the middle turbinal and in the inferior turbinal in so called "chronic hypertrophic rhinitis" The small cell infiltration varied greatly in situa*tion, degree, and character of the cells The great majority of* the cells were lymphocytes The gland ducts in the submucous tissue might be dilated and filled with mucus, degenerated cells, and leucocytes *Cysts were occasionally* found in the submucous tissue filled with homogeneous colloid material and lined by cubical cells The great dilatation of vessels characteristic of acute inflammation was not present in chronic cases to the same extent Thickening of the vessel was observed in one case and in another hyaline change The small cell infiltration was usually very marked round the vessels and old hæmorrhages were not infrequently seen in the submucous tissue as well as deposits of pigment In eight ethmoidal cases *examined osteoclasts were found in* only one instance Bone disease might be present, but it was not an essential change in accessory sinus suppuration and was due to the spread downwards of the inflammatory process In no single case did Dr Fraser find micro organisms in the tissues, although numerous sections of all the cases were examined after staining by Gram s method in addition to the ordinary stains In the discharge lying on the surface organisms could occasionally be seen In nasal polypus and in inferior turbinal hypertrophy the essential condition was one of chronic inflammatory œdema or serous exudation into *the connective tissue spaces under* the basement membrane, the leucocyte infiltration was slight, while the superficial epithelium was as a rule practically normal In ozæna, on the other hand, the change in the superficial epithelium was very marked, large tracts being converted into squamous epithelium and keratinisation of the superficial cells was sometimes present, the glands were atrophied, and there was intense leucocytic infiltration of the submucous tissue, while œdema was absent In the accessory sinuses similar changes might be met with as Dr Fraser found in two of his cases On the other hand, the majority of cases which required radical operation showed changes that corresponded more closely to such conditions as suppurative rhinitis or ozæna Dr Fraser believed that the latter was merely an advanced stage of the former, and he strongly suspected that cases of catarrh of the accessory sinuses were much more common than were usually supposed and that the position of the ostia, while it rendered infection *of the mucosa of the sinus difficult, also* tended to prevent the spontaneous cure of a severe sinus infection Dr Fraser thought that it was possible to show that the changes in the accessory sinuses were similar to those in the nose and that the difference between catarrhal and suppurative processes was only one of degree and that *there were borderland cases In conclusion, Dr* Fraser suggested that in the classification of acute and chronic simple inflammatory processes in the upper respiratory tract (including the middle ear cleft) it would be well to consider the changes not only in the submucous *tissue but also in the epithelial covering Under the* heading of "catarrh' might be included cases with œdema of the submucosa, with little or no alteration of the superficial epithelium and only slight leucocytic infiltration of the submucous tissue Under the head of "suppuration" might be included four more or less distinct conditions (1) cases with little or no œdema and only slight epithelial changes, but with marked leucocytic infiltration, (2) cases similar to the above except that the epithelium had undergone metamorphosis or was almost entirely absent over large areas, (3) cases with marked œdema and leucocytic infiltration but with slight epithelial changes, and (4) cases with marked œdema and leucocytic infiltration but with extensive *changes in the epithelial layer —Dr P* MCBRIDE, Dr A LOGAN TURNER, and Mr HENRY WADE took part in the discussion

Specimens were exhibited by Mr J M COTTERILL, Dr ALEXANDER BRUCE, and Mr *STILES*

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY —A provincial meeting of this society was held at Torquay on May 8th —At 5 P M the Fellows were received at the Natural History Museum by Dr T Horton, President of the Torquay Medical Society, and by many members of the profession of Torquay Dr Horton in a short speech, gave a welcome to the society, and the President, Dr E Solly, returned thanks —Dr Thomas Dunlop medical officer of health of Torquay, read a paper on the Climate of Torquay —The President proposed, and Dr Orwin seconded, a vote of thanks to Dr Dunlop —Dr G W Hamilton *Cumming* then gave directions as to the points of interest in the town —In the evening the Fellows dined together at the Grand Hotel The company numbered about 40 Fellows and ladies and about 40 members of the profession of Torquay, as well as the Mayor, Colonel Spragge; the lord of the manor, Colonel Carey; and the President of the Natural History Society, Major Elwes.—The toast of "The Town and Corporation and Medical Profession of Torquay" was proposed by the President and responded to by the Mayor and Dr. Powell.—The toast of "The Society" was proposed by Dr. Horton, and was responded to by Dr. Leonard Williams and Mr. C. R. B. Keetley.—An excellent concert and conversazione followed the dinner.—On Sunday, May 9th, the Fellows were taken for a long drive on Dartmoor, passing through Bovey Tracey, and took luncheon at the Watershed.—After luncheon the President proposed, and Dr. J. Braithwaite seconded, a vote of thanks to the medical profession of Torquay, especially to those who had taken a very active part in the reception, including Dr. Hamilton Cumming, Dr. Dunlop, Dr. W. W. Stabb, Dr. W. Odell, and Mr. H. K. Lacey.—Mr. Lacey replied.—The party on the return journey took tea at Chudleigh.—The meeting was a great success and proved most enjoyable and instructive.

Reviews and Notices of Books.

The Interpretation of Radium. By Frederick Soddy, M.A. With illustrations. London: John Murray. 1909. Pp. 256. Price 6*s.* net.

This book contains the substance of six lectures delivered at the University of Glasgow last year, and, as might be expected from the fact that the lectures were free, popular in character and illustrated by experiments, the collected work supplies the answers to a number of questions which many interested and intelligent persons will be found daily asking as to the kind of investigation which has led to the present position of radio-active studies, and as to the meaning of the new terms employed in radio-active parlance. The science is a new one and its votaries have really had small opportunity of rendering a coherent account of the results attained or of offering an intelligible interpretation of them to the layman. Besides, the pursuit of the study has opened up such a fascinating experimental field as to have rendered its investigators breathless, so to speak, and powerless to generalise upon the advances made. But what was at one time an almost wildly exciting pursuit has now been resolved into a steady, patient toil after the wonderful secrets which the study of this direction of Nature's endowments promises to reveal. Men have paused and have taken time to record the results and to collect such facts as are calculated when put in order to render the work valuable as a whole.

Mr. Soddy's exposition is admirably clear, and it is not difficult to see that his principal object in delivering these lectures was to present the subject in non-technical language, whilst so carefully has he brought together such facts and pieces of evidence as research has placed at his disposal that no link is left out in the chain of a remarkable story. The publication of the lectures in book form has given him the further opportunity of rearranging and largely re-writing the subject matter in order to secure continuity of treatment. To give an indication of the interesting questions discussed reference may be made to some of the interrogations with which he heads the sections of certain chapters. The following serve as examples: From Where Does the Energy of Radium Come? How is it there is any Radium Left? What is the Ultimate Product? (of disintegration). Are the Metals Changing like Radium? Why is Radium Unique among the Elements?—and so forth. He certainly gives rein to ideas which some may be tempted to call merely speculative in his treatment of these inquiries, but his arguments have the merit of logic behind them, and it is hard to take the position of the absolute sceptic in these days of intense scientific progression. To the philosopher's stone there was accredited the power not only of transmuting the metals but of acting as the elixir of life. Mr. Soddy finds belief in such a stone to be "a perfect and but a very slightly allegorical expression of the actual present views we hold to-day." In energy is the life of the physical universe, "and the key to the primary fountains of the physical life of the universe to-day is known to be transmutation. Was, then, this old association of the power of transmutation with the elixir of life merely a coincidence?"

Again, is the teaching of recent science, which is in favour of the steady upward progress of the race, irreconcilable with the view of tradition of the fall of man from a higher former state? "A race," writes Mr. Soddy, "which could transmute matter would have little need to earn its bread by the sweat of its brow. If we can judge from what our engineers accomplish with their comparatively restricted supplies of energy, such a race could transform a desert continent, thaw the frozen poles, and make the whole world one smiling Garden of Eden. Possibly they could explore the outer realms of space, emigrating to more favourable worlds, as the superfluous to-day emigrate to more favourable continents. One can see, also, that such dominance may well have been short-lived. By a single mistake the relative positions of Nature and Man as servant and master would, as now, become reversed, but with infinitely more disastrous consequences, so that even the whole world might be plunged back again under the undisputed sway of Nature, to begin once more its upward toilsome journey through the ages. The legend of the Fall of Man possibly may, indeed, be the story of such a past calamity."

All these questions are asked in a philosophical spirit, showing neither credulity nor pedantic scepticism. Mr. Soddy's "Interpretation of Radium" is a charming and entertaining volume.

Insanity in India. By G. F. W. Ewens, M.D. R.U.I., Major, Indian Medical Service. Calcutta: Thacker, Spink, and Co. 1908. Pp. 347. Price 12*s.* net.

Major Ewens has had considerable experience of the subject upon which he writes and is intimately acquainted with the practice of psychiatry in India. It is striking to note how very small is the number of the insane population in India as compared with the numbers of the insane in the populations of Western nations. To account for this, Major Ewens adduces the greater simplicity of life, the effect of climate, tradition, and training in rendering the people fatalistic and patient, and lastly, the fact that as very many insane persons are untreated there is probably a great percentage of mortality among them, and consequently the establishment of a natural check upon the transmission to posterity of the tendency to the disease. Another striking peculiarity in the incidence of the disease is the smallness of the numbers of affected females—namely, very nearly as 1 to 5 of affected males. This the author attributes for the most part to the way in which disease occurring among women is studiously concealed.

It appears that, so far as the asylum population is concerned, cases of mania far outnumber other varieties of insanity. Simple melancholia is scarcely seen, for persons so afflicted are conveniently retained at home and are allowed to do as they will. If they do show any troublesome tendency they are tied to the leg of a bedstead or to a tree, and at intervals bled or treated by charms or by other methods which are more highly esteemed among the people than is any form of treatment received at an asylum, no matter how sedulous and sympathetic it may be. Superstition interferes, even as it does in certain circles in this country, with efficient treatment. Given an adhesion to religious practices, the most extravagantly insane acts are condoned as those of a god-inspired man. The author quotes the case of a poor feeble old woman who begged the authorities to give her back her helpless, filthy, and demented son, as she wished to put him in the gate of the village to be consulted as an oracle. In another case the patient was so insane as to be incomprehensibly incoherent, and so deficient in control that he once committed a murder, but was nevertheless regarded by the whole of Lahore, Hindoo and Mahomedan alike, as a holy and powerful man who could, if so inclined, grant his applicants any favour, and was visited daily, not only by the poor, but also by the rich merchants, and even by graduates and native medical men trained by Europeans, men who could for examination purposes discourse learnedly on the causes and symptoms of this very disease, but whose sentiments and superstitions were more powerful than all their learning in governing their conduct.

Marriage in India is contracted in very early life, but there is nothing to bear out the assumption that the offspring of such marriages are mentally defective. Indeed, healthy children are in these cases plentiful and idiots are rare. Major Ewens has written special chapters upon Opium, Indian Hemp, Malaria, and Sunstroke in connexion with insanity. He is of opinion that opium, *per se*, never directly causes insanity. In the Punjab opium eating is such a widespread habit that, had it any direct power of causation, the author is quite certain that some cases would have come under his observation, but as a fact no single clearly established case has come to his notice, and he confidently asserts that the use of the drug has no permanent mental effect. A short chapter contains an account of the law relating to Insanity. A wholesome feature of the law as administered in India seems to be its simplicity.

The book should prove a useful one to physicians practising psychiatry in India, but we cannot refrain from expressing a regret that the author has not paid a little more attention to literary style.

Diseases of the Nervous System for the General Practitioner and Student. By ALFRED GORDON, A.M., M.D. Paris, Associate in Nervous and Mental Diseases, Jefferson Medical College, &c. London: H. K. Lewis. 1908. Pp. xii.-487. Price 12*s.* 6*d.* net.

THE author informs us in the preface to this book that it was written in response to the "continuous complaint" of students and general practitioners that they cannot get hold of a book which gives them a plain and practical account of the diseases of the nervous system. The complaint is not a very reasonable one and we have not heard it often. We do not ourselves feel sure that this book, though written for the very purpose, is well adapted for the needs of students, as we believe that what they most require is a clear account of the elementary facts upon which the broad diagnosis of the nature of nervous lesions is based, such as the distinction between the phenomena of lesions of the upper and lower segments respectively of the motor tract, a well-devised system of routine examination of all cases to bring out the salient features, and a careful study of some of the affections most commonly met with in practice. In this book we have first an adequate chapter on the anatomy of the nervous system, illustrated by figures taken mostly from Morris's "Anatomy"; this is followed by a very brief account of the method of examination to be adopted, extending over barely 15 pages, of which six are devoted to electrical testing and in which no account is apparently taken of the mental condition of the patient; then follow chapters dealing with special affections. The list of conditions dealt with is very full, including not only the diseases usually recognised as nervous, but also some not generally so classified, such as Graves's disease, myxœdema, achondroplasia, acromegaly, and so forth.

We feel that for students, at all events, the space available would have been better occupied by fuller accounts of common conditions, the affections just mentioned being omitted and also some of the rarer affections such as Dubini's chorea or cerebellar heredo-ataxia. The very fulness of the list of maladies may, however, constitute a virtue in other eyes. There can, however, hardly be a difference of opinion as to the author's habit of frequently referring the reader to his writings in the medical journals, as neither students nor general practitioners can be supposed to have leisure for this form of research.

The book is well printed, though we are surprised to find American forms of spelling, such as "fibers," "anemia," and "hemorrhage," in a volume issued by an English publisher. It may be useful as a book of ready reference for the teacher of nervous diseases, scarcely for the direct perusal of his class.

Medicine and Surgery. Vol. X., Thiersch— William Green and ol. X.) 609. Price 15*s.* each volume.

NUMEROUS interesting articles appear in Vol. IX. of this publication. Of those which did not appear in the "Encyclopædia Medica" two may be specially referred to. One on the Medical Examination of Schools and School Children, by Dr. W. Leslie Mackenzie of Leith, is of considerable importance at the present time, as much attention has been publicly drawn to the subject. An interesting account is given of the various commissions which have investigated and reported on the matter in this country, and a reference is made to the measures which have been adopted on the continent. Dr. Mackenzie maintains that medical inspection of school children is no isolated phenomenon, but "part of a world movement towards personal hygiene." Hitherto, he points out, the energies of the public health movement have been mainly exercised in securing a good environment. "The new public health departure of the twentieth century is the effort to increase the capacity and fitness of the organism." We endorse his statement that the fundamental proposition of this movement is that the early nurture of the child is a primary factor in the development of the adult. Hitherto it has been assumed that the children are normal, but unfortunately this assumption has been upset by masses of facts to the contrary. The ignorance of parents in regard to the ordinary necessities of a healthy life is astounding, and doubtless the care which is to be exercised in the future over the children by means of medical supervision will prove of immense advantage to the nation. The other article, which is new, is one on the Status Lymphaticus, by Dr W. H. Wynn of Birmingham. He comments on the various theories that have been advanced to account for the sudden death which so frequently occurs in children suffering from this condition, and maintains that in future investigations on lymphatism especial attention should be directed to the thyroid gland. Recent advances in the knowledge of syphilis have been taken notice of in a contribution by Mr. D'Arcy Power dealing with the causal agent of that disease—the spirochæta pallida—and the serum diagnosis of the malady.

Volume X. brings the work to a conclusion. It contains, amongst numerous other articles, a group of contributions treating of the Morbid Conditions of the Uterus, and a long paper on Pathological Changes in the Urine by Dr. A. E. Garrod and Dr. J. H. Drysdale. The articles on Toxicology (Dr. J. Dixon Mann) and Dangerous Trades (Sir Thomas Oliver) are also worthy of notice.

The whole publication forms a valuable work of reference for those engaged in general practice. The articles are for the most part full and well written, and although doubtful theoretical points are not discussed at any great length, yet the remarks on diagnosis and treatment are all that can be desired—in other words, the Encyclopædia is essentially useful for practical work.

The Operations of General Practice. By Edred M. Corner, M.A., M.C., M.B. Cantab., B.Sc. Lond., F.R.C.S. Eng., Surgeon in charge of Out-patients at St. Thomas's Hospital, and to the Children's Hospital, Great Ormond-street; and H. Irving Pinches, M.A., M.B., B.C. Cantab., M.R.C.S. Eng., L.R.C.P. Lond., Clinical Assistant to the Children's Hospital, Great Ormond-street. Second edition, revised and enlarged. London: Henry Frowde and Hodder and Stoughton. 1908. Pp. 338. Price 15*s.* net.

The very rapid sale of the first edition of this book shows that it has met a demand, and this second edition contains several alterations, and especially a chapter on new operations. We might repeat all the favourable opinions which we expressed on the first edition. It is a thoroughly good book and likely to prove very useful for those for whom it is intended. It becomes nowadays increasingly difficult to draw a line between those operations which are suitable for a general practitioner to perform and those which should be undertaken only by a surgeon who devotes himself specially to operative surgery, which is another way of saying that under the modern curriculum a very large number of men start their professional careers with a fine surgical equipment. Certainly there is little included in this treatise which would be beyond the powers of the general practitioner who has had an opportunity of putting with sufficient frequency into practice what he has learned, read, and seen. In the section dealing with incisions the authors say that it is important that a cut should not be "shelving"; they do not seem to be aware that shelving incisions are followed by less conspicuous scars than those which follow incisions made with a knife held perpendicularly—the fact that our criticism is limited to such remarks as this and the one that follows sufficiently shows our estimate. The lists of instruments required at different operations are likely to be useful, but everyone who operates should remember that it is not rare for operations to prove more difficult and complicated than was thought probable; it is therefore desirable for the surgeon always to have in reserve at an operation any instruments which may be required.

Atlas und Grundriss der Gerichtlichen Medizin. (*Atlas and Rudiments of Legal Medicine.*) Herausgegeben von Dr. Georg Puppe. Two volumes: Vol. I., pp. 692; Vol. II., pp. 335. Price M.20. München: J. F. Lehmann's Verlag. 1908.

This work is practically a new and considerably enlarged edition of the "Atlas of Legal Medicine" by Dr. E. von Hofmann, which was published in 1898. The letter-press has been considerably amplified and many new illustrations have been added. There are now 70 plates in colours and 204 illustrations in black. We believe that the value of a work on medical jurisprudence is considerably added to by a copious employment of illustrative cases and good illustrations. The volume now before us contains a large number of reproductions of photographs and original drawings of various lesions and pathological conditions taken directly from actual cases, and its practical utility has gained much thereby. The illustrations are well chosen and beautifully reproduced, and every subject comprised in legal medicine is represented. An English translation of Dr. Hofmann's work was made, and we hope that the same course will be taken in reference to Dr. Puppe's work. Unless translated the information contained in it can only be appreciated by comparatively few English readers, but as a work of reference as well as a text-book it deserves a large circulation.

LIBRARY TABLE.

A Manual of Surgery for Students and Practitioners. By William Rose, M.B., B.S. Lond., F.R.C.S. Eng., Emeritus Professor of Surgery and Member of Council, King's College, London, and formerly Senior Surgeon to King's College Hospital; and Albert Carless, M.S. Lond., F.R.C.S. Eng., Professor of Surgery in King's College and Surgeon to King's College Hospital; Examiner in Surgery to the University of London and to the Victoria University of Manchester. Seventh edition. London: Baillière, Tindall, and Cox. 1908. Pp. 1376. Price 21*s.* net.—We have had the pleasure on many previous occasions of noticing the issue of new editions of this Surgery, and on each occasion we have been able to praise the general character of the work, and the efforts of its authors to make each succeeding edition fully representative of the surgery of the day. It is doubtful whether at any previous period the progress of surgery has been more rapid than at present, and this fact entails a great strain on the writers of text-books who endeavour to keep them up to date. The authors of this Surgery have been very successful in revising their book, and it is now, as it has been ever since its first appearance, a trustworthy guide to the student and practitioner. The compass of surgery is so vast that some compression is needed to squeeze the whole subject even into 1400 pages, and some sacrifices must be made, but we would ask the authors to do their utmost to prevent the further enlargement of the book. Each issue sees an increase in size and for practical purposes the work can grow too large. We have nothing but praise for the book, and the interesting preface by Mr. Carless shows that he also has a due appreciation of the difficulties of including in a text-book all that should be present while keeping to a reasonable size. Excisions may, however, be possible even if additions are necessary. He would be bold who would venture to predict the position of surgery 20 years hence. We may be sure that many new operations will have been devised and performed, but it is also possible that some present operative procedures will have been rendered unnecessary by inventions and discoveries of other methods of treatment.

Atlas der Syphilis und der Venerischen Krankheiten, mit einem Grundriss der Pathologie und Therapie derselben. (*An Atlas of Syphilis and Venereal Disease, with an Introduction to their Pathology and Treatment.*) Von Hofrat Professor Dr. Franz Mracek in Wien. Second enlarged and improved edition, with 81 coloured plates after original water-colour drawings by A. Schmitson. München: Verlag von J. F. Lehmann. 1908. Pp. 218. Price M.16.—Lehmann's Hand Atlases are too well known to need much praise, and one of the best of them is this volume dealing with syphilis and other venereal diseases. So far as these affect the skin and mucous membranes, they lend themselves readily to pictorial representation, and the employment of colours increases enormously the value of the drawings. In this country it is only a very large circulation which can render possible the sale of 81 coloured plates and a text-book for 16*s.*, and many of our authors must wonder how these things are managed in Germany. The work does not deal with the syphilitic lesions of the bones and other deep structures, so far at least as the illustrations are concerned, but the text does give a brief account of these. The student who reads German cannot have a better series of plates for the study of cutaneous and mucous manifestations of venereal disease.

JOURNALS AND MAGAZINES.

Proceedings of the Royal Society of Medicine. Vol. II., No. 6 (April, 1909). London: Longmans, Green, and Co.—Amongst the communications to this volume of the Proceedings which have not been reported already in THE LANCET are the following. In the Clinical Section a case of malignant tumour in the spinal meninges, with invasion of the cord, secondary to carcinoma of the mammary glands, with other metastases, by Dr. H. Macnaughton-Jones. In the Dermatological Section are reports of cases of urticaria pigmentosa in a girl, aged 10 years, and of trophic lesions in a boy of four years, by Dr. J. L. Bunch; of a doubtful case, possibly sclerodermia of the penis, by Dr. E. G. Graham Little; of acne varioliformis in a man, aged 37 years, by Dr. T. Colcott Fox; of a case showing the curative effects of x rays on scar keloid in a boy of six years, illustrated by reproductions of photographs of the boy before and after this treatment was adopted, by Dr. J. H. Sequeira; and of a case of syphilitic elephantiasis of the lips, by Dr. A. Whitfield. In the Electro-Therapeutical Section Dr. H. Lewis Jones writes on the treatment of nævus by electrical methods, with notes on 1600 cases. A valuable paper in which the author describes the respective scope of action of electrolysis, the galvano-cautery, high-frequency applications, x rays, and radium in the treatment of nævi, port-wine marks, and stellate veins. In the Laryngological Section Dr. J. Dundas Grant describes cases of Hunterian sore inside the lip of a young woman, of laryngeal tuberculosis improved by galvano-caustic puncture, and of a similar case in which the same treatment has been started. Dr. H. Lambert Lack describes a case of telangiectasis with epistaxis; Mr. W. Stuart-Low a case suggested to be one of thyroid tumour of the tongue; Mr. C. A. Parker a case of chronic infiltration of the larynx; and Dr. G. William Hill a case of crescentic subglottic web or hyperplasia in a syphilitic subject, causing stenosis of the anterior half of the lumen of the larynx. In the Obstetrical and Gynæcological Section Dr. W. Rivers Pollock describes a specimen of bilateral ovarian dermoids removed post mortem from an old lady aged 92 years. Mr. W. Gifford Nash records cases of torsion of a parovarian cyst during pregnancy, of hæmorrhage into an ovarian sarcoma producing symptoms resembling torsion, and of hæmorrhage into the peritoneal cavity following a strain, a case in which the great omentum, infiltrated with blood, was removed by operation. Dr. H. Russell Andrews contributes a case of twin pregnancy in a Fallopian tube; Dr. A. H. N. Lewers, an account of a fibroid tumour spontaneously expelled from the uterus seven and a half weeks after delivery; and Dr. H. R. Spencer two cases of ovarian fibroid complicating pregnancy. The Odontological Section is occupied by a paper of exceptional general interest in which Mr. Ashley Densham reviews the progress of dental science and literature from the earliest ages.

The Birmingham Medical Review.—In the February number of this review Dr. D. C. Lloyd Owen writes on the influence of the sexual organs on affections of the eye in women and suggests a toxic origin for such troubles, the catamenial flow normally eliminating some poison which may otherwise accumulate in the system. Mr. Leonard P. Gamgee discusses the indications for and against removal of the gall-bladder, which should not be done as a routine operation in cases of gall-stones nor in the presence of obstruction of the common duct.

The Bristol Medico Chirurgical Journal.—The fifth annual Long-Fox lecture was delivered by Mr. J. Herbert Parsons on Nov. 5th, 1908, and is published in the March number of this magazine. He deals with metastatic inflammations of the eye, and maintains that sympathetic inflammation is due to invasion by bacteria which are pathogenic only for the eye. Dr. George Parker writes on transient cerebral paralyses, many of which he believes to be due to localised anæmia of the brain, and Mr. A. L. Flemming on vomiting connected with anæsthesia. An interesting account of Thomas Dover, physician and merchant adventurer, is given by Dr. J. A. Nixon, who defends our ancient colleague against the accusation brought by Professor Osler that he was a buccaneer who was thorough both in medicine and piracy. A series of six articles is devoted to the merits and demerits of milk.

The Edinburgh Medical Journal.—The late Sir William Gairdner, who suffered from heart-block and the resulting symptoms known as the Stokes-Adams syndrome, kept some record of his malady, and this historic instance of the condition is discussed by Dr. G. A. Gibson and Dr. W. T. Ritchie in the April issue of this journal. Dr. R. W. Philip gives an interesting and useful account of the proceedings of the International Congress on Tuberculosis at Washington, which was notable for the increased favour shown to treatment by various forms of tuberculin. Among these Béraneck's preparation seems to be coming to the fore.

The Dublin Journal of Medical Science.—In the April number Dr. Walter G. Smith records an unusual case of Lupus Mutilans, in which the destruction of the extremities of the fingers resembled the lesions of leprosy. Illustrations are given of the deformity produced and skiagrams of the bony changes accompanying them. Sir John Broadbent writes on Prognosis in Valvular Disease of the Heart and Sir Charles A. Cameron on an Outbreak of Typhoid Fever caused by Infected Milk.

The Medical Chronicle.—Lesions of the diaphragm are dealt with in two articles in the April issue of this journal. In the first Dr. E. B. Leech and Dr. C. H. S. Redmond narrate two cases of Congenital Diaphragmatic Hernia and discuss the phenomena of this condition, which is seldom recognisable by symptoms and signs during life. In the second Mr. E. D. Telford records two cases of Rupture of the Diaphragm, in one of which the patient lived 91 days after the accident and attended to her ordinary duties. Dr. E. M. Brockbank gives post-mortem notes of the cases of aneurysm of the aorta which have occurred in the Royal Infirmary, Manchester, during the last 40 years.

The West London Medical Journal.—A clinical lecture by Dr. Seymour Taylor on Epilepsy published in the April issue of this magazine calls attention to some nervous conditions allied to ordinary epilepsy, especially to cases of nocturnal, and occasionally of diurnal, enuresis. Dr. E. Furniss Potter writes on Submucous Resection as an Operation for Deformities of the Nasal Septum, and Mr. Aslett Baldwin on the Treatment of Appendicitis.

NOTIFICATION OF BIRTHS ACT.—The Brighton town council on May 6th decided to adopt the Notification of Births Act and to appoint a female to act as health visitor and superintendent of midwives at a salary of £80 per annum. The sanitary committee, on whose recommendation the Act was adopted, met with considerable opposition on the ground of the additional burden on the rates, but eventually carried its point by a large majority. It was stated during the discussion that 132 authorities had now adopted the Act.

school and also a block of the other school. The average time taken to cure a case has been reduced from some 18 months to three and a half months. In the ringworm school in Paris the cost per child has been reduced from 2000 francs to 260 francs, that is to say, to almost one-eighth part of the former cost. It is thus a means of great saving, not only in the cost of treatment, but in the time during which the child is unable to associate with healthy children. The same method is applicable to favus, and this is of importance, for the free admission of diseased aliens is bringing us yearly large numbers of children suffering from this disease, which is especially prevalent amongst Polish and Russian Jews. The London County Council is proposing to introduce the x ray treatment of ringworm, and all who are competent to decide the question from a practical knowledge of the subject are agreed that it is by far the best method of treatment with which we are at present acquainted.

The questions here naturally arise:—Is the x ray treatment of ringworm entirely free from risk? Is it not possible that, eminently successful though it may be in removing the disease, it may produce harmful effects which may manifest themselves later? The public imagination has been stirred in this direction by a communication to the *Times*, in which the fear is expressed that the delicate brain of the child may be damaged by the x rays, so that, even though no harmful effects may appear at the time, the rays may so impair the cerebral tissue that its growth will be mischievously affected and its development checked or even rendered impossible. Those who would maintain such views point to the x ray burns and the malignant growths which have appeared in those who have been much exposed to x rays. We are fortunate to be able to print in this number of The Lancet two papers bearing on the question of the x ray treatment of tinea, one by Dr. J. M. H. Macleod and the other by Dr. H. G. Adamson, and they are based on an extensive personal knowledge of this method of dealing with ringworm. The essential principle of the modern method is the accurate adjustment of the dose of x rays, so that the desired effect, the removal of the hairs of the area treated, shall be produced with unfailing certainty, but so that no excess of rays can be administered. In this way the dermatologist can be certain of not producing any permanent alopecia of the scalp and of not causing any x ray burn. The only reaction produced is a transient erythema, which disappears even before the hairs have fallen from their follicles. It is clear that care and skill are required to produce the beneficial, and only the beneficial, results, and at first occasionally the reaction was excessive, sometimes apparently from the use of incorrect pastilles, but these undesirable effects do not appear now, and the skilled operator can guarantee the thoroughness and innocuousness of the treatment.

With regard to the harm that it is suggested may be done to the growing brain of children, what evidence have we that any such harmful effect is ever produced? The *only answer that can be given is that there is not a tittle* of evidence that the x rays in small doses such as those administered for epilation in ringworm have ever had the faintest ill-effect on the brain of the child. Even in the letter to the *Times*, to which we have referred, no evidence is brought forward that any harm of this sort has ever been known to follow the use of the x rays. We have been unable to obtain the slightest proof, or even the slightest grounds upon which to found a reasonable suspicion, that these rays exercise any pernicious influence on the cerebral tissue, and we agree with Mr. Chisholm Williams's letter in our columns this week that such scares are very unfortunate. *A priori*, we should not expect any harm to result, for it is rare indeed even for the skin, directly exposed as it is to the rays, to suffer from the single exposure necessary for Sabouraud's method; the sitting is strictly limited in duration and only one application to any part of the scalp is needed. The harmful effects manifested in the skin in the case of x ray workers follow only after a prolonged exposure or after multiple exposures. Dr. Macleod records this week a series of experiments which he has undertaken in order to estimate the proportion of the rays which are capable of penetrating the scalp and skull, and by means of Sabouraud's pastilles it was found that even the thinnest portion of the parietal bone allowed only half of the effective rays to reach the pastille. In the case of the thicker parts of the bone the protection afforded was much greater. The scalp also appears to cut off about 30 per cent. of the rays, so that, even if we do not take into account the meninges, only about 20 per cent. of the x rays can reach the brain through the thin parts of the skull, a conclusion which, we believe, had been already reached by other observers Sabouraud himself, who has used the x ray treatment of ringworm for nearly five years, has never seen any nervous trouble, either temporary or permanent, follow upon it, and with this opinion all other observers agree. It is almost unnecessary to point out that in speaking of the harmlessness of x rays we have assumed that the treatment is carried out by a skilled and careful operator, but that is an assumption that must be made in relation to any important and delicate operation. Provided that due skill and care are employed, the x ray treatment of ringworm of the scalp is without doubt the most thorough and certain of the methods known to us at present, and, so far as our knowledge goes, it is perfectly free from harm.

◆

The Biological Significance of Fever.

The significance of the febrile reaction to infection by microbial agencies has been much discussed, and in common with many of the problems in pathology has of late been considerably elucidated by experimental researches into the nature of the protective mechanisms of the body and into the production of antibodies. Owing to the fact that the raised temperature in fever is the most striking feature in the febrile reaction the term fever has come to be used in a double sense, being sometimes restricted to that raised temperature, at others employed to designate the whole series of systemic disturbances which should more appropriately be referred to as the febrile state. Moreover, since an elevation of the body temperature may be produced by a variety of conditions, independently of any specific bacterial infection, such as by exposure to very high external temperatures, by drugs, by injuries to or diseases of the nervous system, and by the injection of ferments and tissue extracts, it is necessary to restrict the term "fever" to that form produced by an infective agent or by its toxin, using the term "pyrexia" as a general expression to include all forms of raised body temperature.

The rôle and significance of the febrile temperature or fever in the organism in regard to infection is discussed in an interesting paper by Dr. Fr. Rolly of Leipsic, published in the *Munchener Medizinische Wochenschrift* of April 13th. He points out that by some authorities the raised temperature has been regarded as only productive of harm, by others it has been described as a beneficial adaptation on the part of the organism to combat the disease-producing agent, and by yet others as a condition having both harmful and useful aspects. The work of Liebermeister, who attributed the chief dangers of the febrile state to the raised temperature, and referred the parenchymatous changes in the organs and the general disturbances of function to the same cause, resulted in the general application of antipyretic measures in the treatment of prolonged and continuous fevers. So long ago as 1882, however, Unverricht expressed the opinion that there was no convincing proof of the harmful nature of the febrile temperature, and suggested that, on the contrary, it was possible that it was a useful reaction on the part of the organism against the cause of the fever. Dr. Rolly reviews the experimental researches which have been carried out to differentiate between the effects of the febrile temperature and those of the infective agent or its toxins, and adds the results of some special experiments devised by himself and his collaborator, Dr. Meltzer. In regard to the parenchymatous changes produced in organs he concludes that these are the *result of the infective agent, and that the raised* temperature plays little or no part in their production, probably none unless the temperature is greater than 40° C. Considering next the increased destruction of protein material in fever he finds that, although a high temperature does lead to increased metabolism, with temperatures under 40° C. the increase is almost negligibly small compared with that induced by the activity of bacteria and their toxins. This is determined by comparing the excretion of nitrogen in animals with increased temperature due to artificial overheating, or to lesions of the nervous system producing hyperthermia, with that of animals of the same species suffering from fever due to infection. By similar methods a like conclusion is arrived at in regard to the loss of weight and loss of appetite associated with the febrile state. The increased frequency of the pulse and of respiration, on the other hand, is to be attributed to the increased temperature in fever, and probably in most instances to this cause alone Whether this reaction is beneficial or harmful Dr. Rolly finds it difficult to determine, since on the one side it is possible that the increased circulation may assist in the more rapid elimination of the infective agent, whereas on the other the increased action may lead to cardio-vascular weakness. The vaso-motor disturbances in fever appear to be due to the infective agent, and not to the raised temperature, since Welch has shown that in animals with artificial hyperthermia the functions of the heart and vessels appear intact and blood pressure remains of normal height. In regard to the effects of elevation of the body temperature upon the functions of the nervous system it seems to be established that slight degrees of headache, restlessness, and insomnia may result, but any serious disturbance associated with fever, especially delirium and other disturbances of consciousness, are, according to Dr. Rolly, to be attributed to the infective agent and not to the temperature. Considering the changes in the blood he found in collaboration with Dr. Meltzer that simple elevation of the body temperature causes a diminution in the percentage of hæmoglobin to the extent of 10 to 15 per cent. after periods varying from four to 18 days. The red corpuscles were as a rule not diminished in number, although the leucocytes might suffer a slight increase. These results confirm in the main the observations of Werhovsky on the same question, and are considered to indicate that any severe blood changes, especially in the red and white corpuscles, are the result of the activity of the infective process rather than of the febrile temperature.

Investigations were also carried out to try to discover proof of any beneficial influence of the raised temperature upon the course of an infection. Unverricht suggested that the febrile temperature exerted a damaging influence upon the growth of the infective bacteria, and supported his view with an observation made by Pipping that pneumococci were hindered in their growth upon bouillon by exposure to a temperature corresponding to that found in fever. Dr. Rolly, working with Dr. Meltzer, found, however, that whatever might be the effect upon the growth of the bacteria in artificial media there was no evidence of a directly deleterious effect of the febrile temperature upon *their growth in the living organism. They, therefore,* attacked the problem from another standpoint and endeavoured to find out the influence of temperature upon the course of artificial infections in animals, but did not obtain concordant results until they produced infection by repeated injections of less than the minimal lethal doses of the disease-producing agent instead of one lethal dose, thus endeavouring to approximate the conditions of infection more closely to those of natural infection in man. They then found in a majority of cases evidence of a beneficial effect of the fever upon the course of the infection. They next studied the effects of the raised body temperature upon the known protective processes of the body. Starting with phagocytosis or the ingestion of bacteria and working with human leucocytes they found that their phagocytic power reached a maximum at about 39·5°-40° C., but that at temperatures of 41·5° C. and higher this power rapidly diminished. Since the phagocytic power is greater at temperatures above normal than at the normal level they conclude that in infections where phagocytosis plays a part in protection the raised temperature is beneficial and assists that process Next as regards the specific protective substances formed *in response to bacterial invasion the* agglutinins are easy to measure quantitatively, and they found in rabbits that these substances are formed more school and also a block of the other school. The average time taken to cure a case has been reduced from some 18 months to three and a half months. In the ringworm school in Paris the cost per child has been reduced from 2000 francs to 260 francs, that is to say, to almost one-eighth part of the former cost. It is thus a means of great saving, not only in the cost of treatment, but in the time during which the child is unable to associate with healthy children. The same method is applicable to favus, and this is of importance, for the free admission of diseased aliens is bringing us yearly large numbers of children suffering from this disease, which is especially prevalent amongst Polish and Russian Jews. The London County Council is proposing to introduce the x ray treatment of ringworm, and all who are competent to decide the question from a practical knowledge of the subject are agreed that it is by far the best method of treatment with which we are at present acquainted.

The questions here naturally arise:—Is the x ray treatment of ringworm entirely free from risk? Is it not possible that, eminently successful though it may be in removing the disease, it may produce harmful effects which may manifest themselves later? The public imagination has been stirred in this direction by a communication to the *Times*, in which the fear is expressed that the delicate brain of the child may be damaged by the x rays, so that, even though no harmful effects may appear at the time, the rays may so impair the cerebral tissue that its growth will be mischievously affected and its development checked or even rendered impossible. Those who would maintain such views point to the x ray burns and the malignant growths which have appeared in those who have been much exposed to x rays. We are fortunate to be able to print in this number of THE LANCET two papers bearing on the question of the x ray treatment of tinea, one by Dr. J. M. H. MACLEOD and the other by Dr. H. G. ADAMSON, and they are based on an extensive personal knowledge of this method of dealing with ringworm. The essential principle of the modern method is the accurate adjustment of the dose of x rays, so that the desired effect, the removal of the hairs of the area treated, shall be produced with unfailing certainty, but so that no excess of rays can be administered. In this way the dermatologist can be certain of not producing any permanent alopecia of the scalp and of not causing any x ray burn. It is almost unnecessary to point out that in speaking of the harmlessness of x rays we have assumed that the treatment is carried out by a skilled and careful operator, but that is an assumption that must be made in relation to any important and delicate operation. Provided that due skill and care are employed, the x ray treatment of ringworm of the scalp is without doubt the most thorough and certain of the methods known to us at present, and, so far as our knowledge goes, it is perfectly free from harm.

The Biological Significance of Fever.

THE significance of the febrile reaction to infection by microbial agencies has been much discussed, and in common with many of the problems in pathology has of late been considerably elucidated by experimental researches into the nature of the protective mechanisms of the body and into the production of antibodies. Owing to the fact that the raised temperature in fever is the most striking feature in the febrile reaction the term fever has come to be used in a double sense, being sometimes restricted to that raised temperature, at others employed to designate the whole series of systemic disturbances which should more appropriately be referred to as the febrile state. Moreover, since an elevation of the body temperature may be produced by with dilute domestic sewage there is no reason for supposing that its emanations are prejudicial to health. The case is probably very different, however, when drains and pipes are foul or contain dried material; for then it is easily possible *that the air escaping through such channels* may contain impurities *with marked pathogenic* properties. The same may be said when the sewage is allowed to stagnate or decompose, in which case an unnecessary amount of noxious gases which are not normally present under other conditions is discharged, a contingency which if the sewer is in proper working order could not occur. The report, although *not as complete as Professor Delépine* would have wished it, teaches, at all events, the valuable lesson that no fears need be entertained about injurious or pathogenic qualities of sewer air so long as the sewer is properly constructed, acts well, and is not unfairly or improperly taxed.

THE SICULO-CALABRIAN CATACLYSM: REMISSNESS IN RELIEF WORK.

"THE *English-speaking world," writes an Italian contributor,* "by far the promptest and most free-handed in relieving the sufferers from the earthquake of Dec. 28th, 1908, is entitled to know how its largess has been employed and its active sympathy responded to. Sicilians and Calabrians themselves—interested as survivors of the visitation—have but one answer to give to that question, an answer summed up by one of the most authoritative of their number in the sentence: 'Little has been done, and that little badly.' These words of the eminent surgeon and senator Francesco Durante well-nigh a month after they were *uttered in the Upper Chamber of Parliament are still* without practical effect on the *status quo!* Nay, they are as true in the week now passing as when they wound up a debate on the situation in April last. On May 6th Signor Paniano, a prominent member of the Lower House, received the following telegram from Messina: 'For two days we have had rain and snow. The population "accommodated" in the huts—huts without doors, without windows, without tiles—are benumbed and dying of cold. We want to know to what Government we ought to turn for the provisions required. Signed: Martini, Vice-Syndic. Commenting on this appeal, one of the leading Roman journals writes: 'The whole country, which had a primary outburst of sympathetic solidarity in behalf of Sicily and Calabria, should follow that up with a second, not indeed to collect funds, but to insist on the proper application of those already collected.' As if to add a personal, not to say self-interested, motive to that which common humanity ought to inspire in accelerating and intensifying the relief work, a Catanian journal of about the same date as the above-cited telegram, under the title of 'Un Nuovo Flagello' (a new scourge), says: 'A strange, fierce crowd infests the dead city of Messina—a crowd of vermin and microbes, which take by assault the corpses disinterred by the eager avarice of those who, night and day, are grubbing for loot among the ruins,' and after a gruesome description of the maggots and insects subsisting on the putrescent dead, the journal adds: 'Meanwhile a fœtor, heavy as a cloud, destructive as a pestilence, ascends from the vast cemetery.' *There may be* exaggeration in this, as the official organs are fain to plead, but if only half of it be true it constitutes a severe indictment of the efforts, central as well as local, to retrieve a situation appealing, now these four months, to the sympathies of all Italians, not to say of the outlying world. *The official organs referred to make* much of isolated relief work at this or that centre of population to which the survivors have been deported. At Palermo, for instance, something has been achieved, in the Clinica Pediatrica attached to the University Hospital and also in the 'Ospedale dei Bambini' (Children's Hospital). But while 'hand-to-mouth' relief has undoubtedly been practised here and there, and while cases can be quoted of effective assistance rendered to this or that sufferer, the net result is deplorably inadequate to the means and the resources, monetary and other, placed at Italy's disposal by a sympathising and generous world. Unfortunately her record in visitations of a similar kind is by no means unimpeachable—witness the malversation of funds subscribed in Great Britain alone in 1883 for the victims to Venetian floods and Ischian earthquakes! Even as late as 1903, when Calabria succumbed to a 'telluric storm' only less disastrous than that of Dec. 28th, 1908, next to nothing was effected for the sufferers until a 'surprise visit' of the King brought the local authorities to a sense of their duties. It is unpleasant to have to write in this strain, but Italy, if she wants to keep, as she certainly has deserved, the sympathy of the outside world, must henceforth see to it that the help so amply, so promptly vouchsafed has been properly distributed and not, by carelessness, or remissness, or worse, been frittered away in the distribution."

SMOKE ABATEMENT.

THE report recently presented to the London County Council on the smoke abatement question furnishes further evidence as to the source of the evil; and in many particulars this evidence will be found analogous with that which we have brought to the notice of our readers in a practical form from time to time. It is pointed out that apart *from the smoke emitted from trade premises serious* smoke nuisance also arises from private houses. It is estimated that one-half of the smoke in London comes from this source, for which there is no legislative remedy. The emission from each individual chimney may be slight, but in winter probably one million domestic chimneys pour forth smoke daily into the atmosphere, and it is therefore evident that the total volume of smoke must be very great. It has been noticed that some of the densest London fogs have arisen on days when the great bulk of business premises have been closed. A bank of smoke has been *seen to rise to a height of* 3000 or 4000 feet and to be carried by the wind in a sunlight obscuring trail to a distance of 50 miles. Dr. W. N. Shaw of the Meteorological Office says the records show that owing to its smoke London loses half its sunshine in winter and one-sixth in summer. Many people advocate the abolition of the open fire in favour of the closed stove system in use on the continent, but the Public Control Committee in its report remarks that, while undoubtedly the general adoption of such a system of heating would result in a purer external atmosphere, this would be secured at the sacrifice of much of the fresh air indoors, for which open fires, by providing a good deal of ventilation, are largely responsible. The committee looks for a reduction of domestic smoke from the use of open fire grates which secure better combustion of coal, and from the growing use of gas and electricity for heating and cooking. There are nearly half a million gas cooking-stoves employed *in London houses at the present time. To* diminish domestic smoke materially public opinion needs to be educated, and a step in this direction is the instruction which is given to children in the day-schools in the principles of combustion, so as to make them grasp the fact that smoke is not inevitable but often results from the wasteful use of *fuel. The committee* does *not suggest* any action to deal with nuisance from the domestic chimney, but it points out that it may be necessary, unless public opinion brings about some radical improvement, to give serious attention to this grave problem. With a view to collecting and disseminating information the committee recommends that the Council should obtain powers to spend not more than £500 a year in the advancement of measures for the abatement of smoke nuisance. The committee also suggests definite amendments of the Public Health (London) Act, 1891, which experience of the working of the measure has shown to be necessary. The most important of these is a proposal to delete the qualifying word "black" as applied to smoke. It is also desired to bring the premises of the Crown, of local authorities, and of statutory companies under the operation of the statute, and to obtain powers to deal with the nuisance arising from smoke drifting into London from premises situated outside the county boundary. This clause would be enforced by the London County Council, but the Act, as a whole, is administered by the borough councils. The Finance Committee, reporting on the proposals from a financial point of view, raises no objection so far as strengthening the powers of the borough councils is concerned, but it "views with apprehension" any proposal which might involve the County Council in increased expenditure of an unascertained amount. As we have said, the substance of these recommendations will be found in the pages of THE LANCET for the past decade or so as the outcome of several practical inquiries made by us upon the subject.

THE MORTALITY AMONG WORKHOUSE BABIES.

IT may be recollected that the early part of the third chapter of the Minority Report of the Poor-law Commission contained severe criticism of the maternity wards and nurseries of workhouses which had come under the observation of certain of the Commissioners, based partly upon conditions described as existing in them, and partly upon statistics of infantile mortality in workhouses and upon the comparison of these with figures relating to infantile mortality outside the domain of Poor-law relief. So startling were the figures that Mr. F. E. Smith, K.C., called attention to them in the House of Commons immediately by a question addressed to the President of the Local Government Board, and an amplification of the reply then given by Mr. Burns has since been issued by the Board as a Parliamentary paper. The paper criticises the figures of the Minority Report and in turn has been criticised by Mrs. Sydney Webb, one of the four members of the Commission responsible for that report. Mrs. Webb's able letter has appeared in several papers and the statement of the Local Government Board is obtainable through the usual channels at the price of 1*d.* It was pointed out in our first criticism of the Minority Report[1] that discussion as to the accuracy and justice of the figures and the arguments relating to this particular topic was inevitable, and the subject is one well worthy of attention. In the workhouse lying-in wards and nurseries a high percentage of mortality exists, to which and to possible means for preventing it the four Commissioners rightly drew attention; but in dealing with it statistically they relied in part upon figures which were unimpeachable, but which in some degree are open to the criticism of not being upon a sufficiently large scale to make it safe to generalise from them, and in part upon others of a more speculative nature, drawing conclusions from the combination of the two classes. Those conclusions and the data upon which they are based form the subject of the Local Government Board's statement, which Mrs. Webb characterises as a "white-washing report," and as to which it is true that so far as it goes it defends the workhouses, dissenting from the conclusions of the Minority Report. It confines its attention, however, to the subject of Mr. Smith's question—namely, the figures—and does not touch upon the conditions which were described in the Minority Report as existing more particularly in the nurseries and as contributing to, or as responsible for, the mortality to which the figures related. In fact, it seeks to repel only one portion of the attack aimed at the workhouses, for which the Board must accept a measure of responsibility. It points out the importance of considering pre-natal conditions in determining the causes of death among the infants in the lying-in ward of a workhouse infirmary, showing by a table that of 112 infants dying in the first week of life out of 2653 born in London Poor-law institutions 57 were prematurely born, 46 were doomed to early decease by congenital defects, atrophy, debility, marasmus, and inanition, the remaining nine succumbing to other stated causes. As an instance of statistical weakness the Board points out that in dealing with the later life of infants born in workhouses, who either remain in the institution or are taken from it in their first year, the Minority Report assumes that those who left the workhouse within the year had a death-rate equal to those who remained in the institution. Figures thus arrived at are clearly not to be relied upon in controversy, nor are any which are open to the criticism that they are based upon the observation of an insufficient number of cases or upon cases not properly related to those with which they are to be compared. Figures, in short, have to be handled with exactitude, in a spirit as little as possible that of the partisan, and with full knowledge of the circumstances to which they may be traceable. As an instance of what we mean, we take at random some percentages given in a footnote at page 782 of the report, where we read that "the proportion of infantile deaths to the births during 1907 was in the City of London Lying-in Hospital, 26·1 per 1000; in the East-end Mothers' Home, 21·07 per 1000; in Queen Charlotte's Lying-in Hospital, 26·1 per 1000; and in the General Lying-in Hospital, 59·3 per 1000." This might condemn at first sight one of the institutions named as deserving greater censure than the workhouse lying-in wards As it is, it does nothing of the kind, for we neither draw nor suggest any conclusion from it. We also at present do not draw conclusions from all the figures upon which Mrs. Webb lays stress. We are, however, in accord with her when she calls attention to some which on their face are comparable, and we agree that inquiry is desirable as to the cause of serious differences in the rate of mortality where such exist "between adjoining unions in the same towns" or between unions whose circumstances are provably similar. We also observe that the Local Government Board's statement does not cover such allegations of fact as are contained in the first of Mrs. Webb's numbered conclusions, and that it does not deal with corresponding statements on the subject of workhouse nurseries made in the Minority Report, which its signatories are no doubt ready to justify. These questions of fact are capable of independent authoritative inquiry and are fit subjects for it. Moreover, the conditions complained of, if found to exist, are capable of amendment without recourse to legislation and without waiting for boards of guardians to be superseded by other bodies administering the same functions.

DIPHTHERIA AND ANTITOXIN TREATMENT.

OUR Swiss correspondent writes from Zürich that at the request of Professor Kroenlein, professor of surgery at the University of Zurich, Dr. Ph. Schoenholzer, his senior house surgeon, has published an extensive report on 3322 cases of diphtheria treated at the clinique during a period of 28 years. As in 14 of these years the old methods of treatment were employed and in 14 the modern antitoxin treatment, a comparison of therapeutic results is readily available. The antitoxin used for these patients was prepared by the Federal Serum Institute of Bern. Out of 1336 patients treated in the pre-antitoxin period (from 1881 to 1894) 40 per cent., or 534, succumbed to the disease, whereas out of 1986 cases registered from 1894 to 1908 only 13·4 per cent., or 266, died from diphtheria. The mortality of the tracheotomised patients decreased from 66 per cent. during the first period to 14 per cent. under the antitoxic *régime*. The reduction of the death-rate in the other cases was from 32·5 per cent. to 6·8 per cent. The mortality rate varied considerably from year to year—under the old treatment from 27 to 56 per cent., under the new from 5 to 20 per cent.

---

[1] THE LANCET, March 6th, 1909, p. 707

THE HYGIENE OF THE HANDLE AND THE STEM.

THERE is a feature connected with the construction of certain modern drinking receptacles which in some circumstances is hygienically objectionable. We refer to the ordinary plain tumbler or goblet which has neither handle nor stem. It does not require the refinements of bacteriology or chemistry to indicate that in common places of refreshment the tumbler, the stemless glass, or the metal drinking vessel without a handle may readily be a source of contamination to the drinker. It is not customary any longer to drink tea out of a cup without a handle, and there are hygienic reasons in favour of the modern cup. It is surely a transgression against sanitary law or cleanly requirement that the edge or rim (or the space near it) of a drinking vessel is used both for lifting that vessel and for applying it to the mouth in order that the contents may reach the mouth. In public places of refreshment where it is the rule to serve drinks in tumblers, it is common enough to see the glassful of beer or whisky-and-soda handed to the customer by the serving person with his fingers and thumb on the rim—in fact, on that very portion of the glass which comes into contact with the drinker's lips That is an obviously repulsive proceeding and one which should (as it easily can) be avoided. It would hardly be safe to assume that the hands and fingers of the barmaid or barman are scrupulously clean, and therefore the use of the tumbler or the handleless goblet in public places of refreshment is open to objection. We are quite sure that this argument will appeal to all cleanly persons, and that they will agree that it would be much more satisfactory if vessels with a handle were employed in public-houses, or if all glasses were provided with a stem. After all, the function of the stem and handle of drinking vessels is much the same thing, and in view of the above facts glasses either with stems or handles should be reinstalled in those places of refreshment where they have been discarded.

THE HAROLD BARNARD MEMORIAL FUND.

WE have received a circular letter signed by a committee consisting of the Honourable Sydney Holland, Dr. W. J. Hadley, Mr. E. Hurry Fenwick, Dr. A. Dashwood Howard, Dr. R. C. B. Wall, Mr. James Sherren, and Professor Arthur Keith, and stating that soon after the lamented death of Mr. Harold Leslie Barnard a number of his colleagues, friends, and pupils met to determine the best manner in which they could recognise his services to the London Hospital and to the progress of surgery. An examination of the manuscripts, unpublished observations, papers, and drawings which he left behind him made it clear to his friends that they owed him a double duty, not only to keep alive his memory, but to see that the results of his brief but laborious experience, of his keen observation and study, and of his vivid and over-watchful imagination are suitably preserved for the use and advantage of all who serve the cause of medicine and surgery. It is proposed that Barnard's name be perpetuated by the publication of a memorial volume, which will include all his contributions to abdominal surgery. From the time he joined the staff of the London hospital in 1900 he concentrated his energy and ambition on the production of this work, but he died when his task was approaching completion. He had engaged two of his former pupils—Dr. F. Wood-Jones and Mr. Stanley J. A. Beale—to prepare drawings of his specimens for this work; these drawings are of special merit and will enhance the value of the work, but at the same time will add to its cost. It is hoped, therefore, that his friends and pupils will support liberally the attempt to fulfil the ambition of Barnard's career. The cost of publication of such a volume is estimated at £200. In the event of a sufficient sum being subscribed to cover the expense of publication it is proposed that each subscriber should be presented with a copy, but in the event of the total subscription falling short of the cost of publication that only those who subscribe 10*s*. 6*d*. and over should be entitled to a copy, the remaining copies being placed on sale. Mr. Sherren has offered, and the memorial fund committee has accepted, his services as editor of the work. A short biography, with photographs, will be contributed by his friend and pupil, Dr. H. H. Bashford. Dr. Cecil Wall, to whom Mr. Barnard confided his manuscripts and papers, has consented to act for the committee as honorary secretary and treasurer. The committee appeals with confidence to Mr. Barnard's friends and pupils to assist them liberally and promptly by forwarding their subscriptions to the honorary treasurer, at 6, Cavendish-place, Cavendish-square, London, W. This is an appeal which should commend itself strongly to all who knew Mr. Barnard and appreciated his tireless work in the cause of surgery. No more proper monument can be raised to any truly scientific worker than is to be found in his own writings, and we trust that the committee making the present appeal will meet with the support it rightly looks for and will be able to enshrine Mr. Barnard's contributions to surgical literature in a form worthy of the reputation which their author found time in a too short life to win.

AN AUTOBIOGRAPHICAL ACCOUNT OF THOMSEN'S DISEASE.

NOT since Thomsen's classical description of this disease in 1876 has it befallen the physician reporting it to be himself the sufferer. In the *Montreal Medical Journal* for November, 1908, Dr. Arthur Birt of Halifax, Nova Scotia, has devoted an article to the subject of the disease as it occurs in himself and his own family group. The diagnosis was made by the writer while he was still a medical student and it has since been amply confirmed. Ever since he can remember he has been afflicted with a painless stiffness and cramp on first attempting any voluntary movement, especially after rest. When a schoolboy he found this stiffness to be a source of great disability in sports and games All the muscles of the body were liable to the condition, including those of the eye, tongue, and jaw, and since early manhood there has been no appreciable change. At the present time, conformably to the usual rule, the musculature is exceedingly well developed, although no systematic exercise has ever been taken for any lengthened period. The muscles feel firm to the touch, they quickly harden on palpation, and if they are put into strong voluntary contraction they are found for a number of seconds to be of iron hardness, which, however, rapidly passes off. The peculiarity of movement is entirely restricted to voluntary movement; the patient, on rising from a chair to walk away, is checked in his first step by a painless cramp of the extensors, and a similar accident occurs in the other leg before the cramp in the first has subsided. When the second movement forward of the first leg is initiated the spasm has not yet relaxed, but the cramp this time is of less duration, so that with each succeeding stride the period of cramp becomes rapidly less and a normal gait is attained. In shaking hands firmly there is often inability to relax the finger flexion quickly, a trifle, as the writer observes, "which may give rise to misconstruction in ordinary social intercourse." The characteristic electrical reactions of the disease are readily obtained in Dr. Birt's case—viz., marked prolongation of the contraction both to faradism and galvanism, wave-like contractions from cathode to anode with the stabile method of application of the latter; there is also prolonged contraction on mechanical stimulation of the muscles. A sister of the writer suffered severely from the disease and died at adolescence; another sister shows traces of it, and two cousins are definitely affected. In the family there is a very clear neuropathic diathesis.

THE ADMISSION OF WOMEN TO THE DIPLOMAS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

WE have received from Dr. A. S. Morton and Dr. W. G. Dickinson, as secretaries of the Society of Members of the Royal College of Surgeons of England, a copy of a memorial sent by that society to the Home Secretary to protest against the mode of admitting women to the diplomas of the College. which is at present under Mr. Gladstone's consideration, The chief arguments used to support this protest are as follows. (1) That the effect of admitting women under the Act of 1876 will be to create an inferior order of Fellows and Members without any share in the management of the College; (2) that under this Act women Members of the College will be barred for all time from acquiring the position which it is hoped that the Members may ultimately gain in that management; (3) that the adoption of this Act by the Council of the College is a retrograde step in view of the position which women have attained in the medical profession since 1876, and that it is opposed to the policy of all modern Universities; (4) that a difference in policy on this matter between the Royal College of Surgeons of England and the University of London will create an added difficulty in the negotiations in which delegates from those bodies and from the Royal College of Physicians of London are engaged; and (5) that at the last annual general meeting of Fellows and Members a motion was carried unanimously—

> That this meeting is of opinion that women when admitted to the diplomas of the College should have equal rights with men.

It may be of interest to our readers if we add the text of the proposed new by-law, to which previous reference has been made in THE LANCET:—

Section XXVI. Admission of Women.

1. Pursuant to the powers conferred by the Medical Act, 1876, and subject to the provisions therein and hereinafter contained, women may be admitted as Members and Fellows of the College and may obtain Diplomas in Dental Surgery on the same terms and conditions as men; and so far as it is necessary to give effect to this by-law, words in the By-laws and Regulations of the College which import the masculine gender shall also import the feminine gender, and all proper alterations shall be made in the form of the Letters Testimonial, Diplomas, Certificates, [illegible]

2. Women shall not [illegible] not vote at, or take any [illegible] the Council, or atten[illegible] Members (except meet[illegible] Orations), or otherwise take any part in the government, management, or proceedings of the College.

3. Women shall not be eligible as members of the Court of Examiners or for any examinership to which the Council appoint.

One more of the arguments used by the Society of Members in its protest to the Home Secretary is that paragraphs 1 and 2 of this draft are contradictory. We are unable to follow this reasoning. It appears to us that the words "subject to the provisions ...... hereinafter contained" in the first paragraph fully cover the exception made in the second.

THE LONDON COUNTY COUNCIL AND INFECTED EARS.

A FEW months ago[1] we recorded that the London County Council had made arrangements with the Queen Victoria Jubilee Institute for Nurses for the treatment of school children suffering from infected ears. The scheme provided that cards should be given to the parents intimating that free nursing treatment would be provided after a medical man had been consulted. We commented on the somewhat inconsequent action of the Council in prescribing on the card the treatment to be adopted (a course which left the medical man in charge of the case nothing to do but to sign his name) and at the same time adding, "It must be understood that the London County Council will accept no responsibility for the treatment prescribed or given." Other protests have been raised against this form of card, which has accordingly been redrafted. Instead of advising the parent to consult his own medical attendant or to "take the child to a hospital for medical advice," the parent will in future simply be notified that the Council is prepared to provide treatment "if recommended by a medical man." Then on the reverse side of the card a space is provided for the medical man to write his own prescription. As the whole question of the medical treatment of London school children is now under active discussion the treatment of infected ears will doubtless be brought into line with that of other ailments.

"INTESTINAL SAND" DUE TO THE BANANA.

MANY cases of the rare condition termed "intestinal sand" have been carefully investigated, but the subject is still involved in some obscurity. Two forms—true and false—have been distinguished. False intestinal sand is said to be composed of the remains of vegetable food which have resisted digestion with possibly an incrustation of earthy matter. In true intestinal sand such vegetable basis is said to be wanting; there is a much larger proportion of inorganic matter. This sand is therefore supposed to be an intestinal excretion. It is almost always associated with intestinal disorders, usually with membranous colitis. Among vegetable foods the pear is especially apt to produce intestinal sand, as it contains many sclerenchymatous particles which appear in the motions. The banana has been found by American writers to have a similar aptitude. In the *American Journal of the Medical Sciences* for March Dr. J. S. Myer and Dr. J. E. Cook have reported a case and shown that "intestinal sand" may be produced *ad libitum* by eating bananas. They make a very reasonable suggestion which simplifies the whole subject—that all "intestinal sand" is due to vegetable remains, and that when a large amount of salts is deposited the vegetable nucleus is overlooked. The alternative hypothesis that the sand is an intestinal secretion does not account for the 30 to 70 per cent. of organic matter which it has been found to contain. The fact that true intestinal sand is associated with intestinal symptoms Dr. Myer and Dr. Cook suggest is accidental, excepting constipation, which would favour deposition of salts. The association can be explained by the fact that only when intestinal symptoms are present are the fæces likely to be examined and sand observed. Mucous colitis, the disease in which sand has been most frequently observed, is also the disease in which the stools are most frequently examined; but only in a small minority is sand found. The following is the case now reported. A woman, aged 24 years, complained of fulness in the abdomen and chronic constipation. The abdomen was tense and slightly tympanitic. The stools were intimately mixed with small black or brown sand-like granules. A stool was washed through a fine sieve and the greater part of the sand was found in the water. It was brownish and felt gritty. Under the microscope the sand was seen to consist of irregularly shaped more or less oval grains, varying in size from 0·05 to 0·2 millimetre in diameter. They were translucent and varied in tint from light yellow to dark yellow, brownish, and greenish yellow. By reflected light they had a beautiful appearance, resembling variously coloured quartz. They were hard and brittle and were crushed with difficulty under the cover-glass. On applying a strong acid gas was evolved and the sand became of a lighter yellow colour. Chemical analysis showed 17·2 per cent. of moisture; the residue contained 95·8 per cent. of organic matter. The inorganic portion consisted principally of phosphate of calcium. The high proportion of organic matter pointed to a vegetable origin. By ingestion of various vegetables they endeavoured to produce sand artificially, but failed. The presence of a chain of sand with two or three fibro-vascular bundles originating from a common point and separated by a mass of parenchyma cells suggested a remnant of banana tissue. It was then found that on eating one or two bananas intestinal sand could be found in the motions in quantities varying from a teaspoonful to a tablespoonful in the 24 hours for several days, and in cases of constipation for much longer. As a rule, the grains were found singly, but also in chains if the stool was not manipulated too much in washing. If a banana is cut transversely and exposed to the air light brown markings appear on it. Under the action of perchloride of iron they form rapidly as black strands, which under the microscope were found to be identical with the grains of sand in the fæces. These strands are the "milk tubes" of the banana and are composed of cells containing a resin suspended in a fluid rich in tannin. The action of the intestinal secretions on the resin forms the sand.

---

[1] THE LANCET, Feb. 13th, 1909, p. 488.

BOARDS OF GUARDIANS AND PUBLIC VACCINATORS.

FOR many years there has been much dissatisfaction amongst public vaccinators as to the conditions under which they are called upon to do their work, and although a departmental committee which sat a few years ago made certain recommendations, some of which were calculated to improve the position of the officers concerned, the Local Government Board has up to the present only acted upon such of the recommendations as were to the detriment of the public vaccinators. This is not, we think, quite the proper spirit in which a State department which depends so much upon the medical profession for its status in the country should act—that is to say, if the department desires to receive that support from the medical profession without which it would find administration a difficult matter. If there is one thing more than another to be read between the lines of the Royal Commission on the Poor-laws it is the appreciation of the services of the medical profession and a demand for its employment in greater degree than formerly. The duties of the public vaccinator are already sufficiently onerous and, with general slackness as regards the administration of the Vaccination Acts, they are steadily increasing. The most recent development is a growing disposition on the part of boards of guardians to make the post of public vaccinator dependent, as it were, upon that of district medical officer and *vice versâ*, the advantage to the guardians of this fictitious arrangement being that when a public vaccinator who is also a district medical officer resigns his post as public vaccinator because of the smallness of the fees and the difficulties of the position his appointment as district medical officer is also terminated. And conversely, when a district medical officer, who is also public vaccinator, relinquishes his position in the former capacity because it is not consistent with his conscience to supply medical advice and medicine for less than twopence per attendance his contract as public vaccinator is forthwith terminated. Instances of this kind of treatment have recently been brought to the notice of Mr. Burns by the Association of Public Vaccinators, and he has been asked to receive a deputation upon the matter as well as upon the question of the security of tenure of public vaccinators as recommended by the departmental committee already referred to. This request for an interview has, however, been refused, and the petitioners have been told that in the opinion of the Board when the offices of public vaccinator and district medical officer are held together the remuneration of each office should be proportioned to the duty of each office, but that when an officer is required to devote his whole time to public appointments the guardians may properly have regard to the total remuneration which will accrue to him in respect to those appointments. As to the question of security of tenure, the Board states that it has no powers under the existing law to grant such security. Both these replies seem to us somewhat evasive and illogical. The appointments of district medical officer and public vaccinator are quite distinct; according to this ruling of the Board the district medical officer might be called upon to do the vaccinations for nothing, which is, of course, absurd. As to the other point, it is, we presume, common knowledge that fixity of tenure would require legislation, and the public vaccinators in wishing to discuss the matter with the President of the Local Government Board were probably anxious to induce him to introduce a Bill into Parliament giving effect to the recommendation of the departmental committee which either he himself or his predecessor in office must have appointed. The public vaccinators are greatly to be sympathised with. The departmental committee prescribed some stones and some bread. The stones have already been thrown with disastrous effect, but when the public vaccinators ask for the bread the departmental granaries are empty. The attempts which are being thus indirectly made to cut down the pay of district medical officers must be strenuously resisted, more particularly so when this fact is considered in conjunction with the circumstance that greater attention is daily required from these officers and that the cost of living and medical education is steadily rising. If the public medical service of the country is to improve in proportion with the demands made upon it by the public, that service must receive greater recognition by the State than has hitherto been the case.

THE LARYNGITIS OF MEASLES.

IN another column we publish an article by Dr. A. A. Warden, entitled "A Plea for the Use of Anti-diphtheritic Serum in the Laryngitis of Measles." Although we cannot altogether support this plea, yet the communication is of value in drawing attention to a most grave complication of measles—namely, diphtheria. Some degree of catarrhal laryngitis is so common in the course of measles that it can almost be considered a symptom of the disease rather than a complication, and therefore if Dr. Warden's suggestion were adopted—namely, "In the laryngitis of measles do not wait for a bacteriological diagnosis but at once inject antidiphtheritic serum"—this procedure would have to be carried out in nearly every case. If, however, this dictum were to be applied to every instance in which a membranous laryngitis occurs, then Dr.

Warden's suggestion might well be followed. Indeed, it is possible that this is what he intends to imply, and if such be the case we endorse his advice. The membranous laryngitis may be produced by pyogenetic cocci, but this can only be positively distinguished from diphtheritic membrane by bacteriological culture, and much valuable time would be lost in waiting for the result to be received from the laboratory. The success of the antitoxic treatment is considerably greater if it be employed at an early stage of the disease, and therefore practitioners would be taking a wise course in administering the antitoxin in cases of measles in which a membranous laryngitis makes its appearance.

NASAL CRISES IN TABES DORSALIS.

THE day is passed when tabes dorsalis was considered a disease to be limited to the posterior columns of the spinal cord. The field covered by locomotor ataxia in its manifestations has been very greatly extended, till now it is admitted there is no part of the nervous system, central or peripheral, which may not be the seat of the tabetic process. The aspects under which the disease may present itself are so variable that the clinician cannot afford to neglect any of them. In a recent number of *La Semaine Médicale* M. Klippel and M. Lhermitte have directed attention to a little known corner of the tabetic field, one which, however, concerns the general practitioner as much as the professed neurologist. They have written an instructive paper on affections of the gustatory and olfactory apparatus in tabes, and the clinical cases which they quote emphasise once again the extreme importance of recognising that the symptoms for which the patient consults his physician may be but a purely local indication of a much more widespread condition. M. Klippel and M. Lhermitte consider that the nasal crisis of the tabetic may be represented by one of three differing types—viz., sensory, spasmodic, and secretory—although this division is somewhat schematic. The disturbance, of whatever type it be, may occur in those who show a permanent defect in their olfactory sense as well as in those whose smell is normal. The common impairment found in the subject of tabes is partial or complete anosmia, with hypoæsthesia of the face and nasal mucosa, and vaso-motor or trophic changes in the olfactory mucosa itself. In the first variety of nasal crisis the patient feels a pricking sensation at the root of the nose, a disagreeable tickling in his nostrils, and then suddenly experiences a strong and unpleasant subjective odour commonly compared to that of rotten eggs. Occasionally it is associated with an equally unpleasant taste in the mouth. Among the many instances quoted by the authors are cited those described by Mr. Herbert Tilley[1] 14 years ago as three cases of parosmia, and the suggestion is made that they were in reality cases of tabes in which the ordinary symptoms of the condition were not present or not recognised. They do not ignore the occurrence of similar phenomena in intracranial tumours of a particular localisation, but the diagnosis presents no real difficulty. The spasmodic type of nasal crisis is characterised by attacks of sneezing; one of their patients used to notice a sensation of coolness and of pins and needles over the left half of the face and then sneezing set in; it was sometimes accompanied by flashes in front of the left eye and bilateral tinnitus. An instance is given where this form of nasal crisis proved to be the first symptom of tabes. Sometimes the crisis is succeeded by a flow of tears or of mucus from the nose; in practically every case some objective modification of facial or olfactory sensibility can be discovered. Where there are definite vaso-motor or secretory phenomena we are dealing with the third or rhinorrhœic form of nasal crisis. One of the cases concerned a patient with locomotor ataxia, whose attack always began with a series of short abrupt respirations, followed by a bout of sneezing of several minutes' duration. As soon as these spasmodic phenomena ceased, a slightly viscid reddish fluid poured from the nose, soaking a handkerchief in very little time; towards the end of the flow it became clear and much more watery. Examination of the nasal fossæ revealed no abnormality whatever, but there were changes in cutaneous, mucous, and olfactory sensibility. The differential diagnosis of these symptoms may no doubt be difficult, but the discovery of any of the classical signs of tabes is very significant, in particular any notable alteration in sensibility in the distribution of the trigeminal nerve. In one of their cases M. Klippel and M. Lhermitte have found unmistakeable histological changes in the olfactory bulbs. Of the encephalic manifestations of the tabetic process several are, of course, very well known, in particular optic atrophy. Sir William Gowers has drawn attention to the occurrence of "auditory atrophy" in the shape of constriction of the auditory field, and this latest contribution to the subject is equally suggestive and likely to repay research.

AT a meeting of the Royal Society on May 6th the secretary announced that Colonel Sir David Bruce, who is in charge of the Sleeping Sickness Commission at present in Uganda, had cabled to the Society on April 3rd to report that the Commission had confirmed Kleine's observations on the period during which the tsetse fly was capable of transmitting a trypanosome infection. A letter had been received by the Society on April 30th from Sir David Bruce, dated Mpumu Chagwe, Uganda, April 3rd, confirming the telegram, and stating that the Commission had "repeated Dr. Kleine's experiments with *Trypanosoma gambiense* and *Glossina palpalis*, also with a trypanosome of the dimorphon type and the same Tsetse-flies, and found the flies infective after 16, 19, and 22 days."

THE EARLY RECOGNITION OF UTERINE CANCER.

AT the annual meeting of the British Medical Association at Exeter in 1907 the Section of Obstetrics and Gynæcology adopted a resolution requesting the Council of the Association to appoint a committee to consider the best means of disseminating knowledge of the importance of the early recognition of uterine cancer. That committee presented a report which was considered, and generally approved, by the same section of the annual meeting of the British Medical Association in Sheffield in 1908. At its meeting on April 28th, 1909, the Council of the British Medical Association approved for publication the appeals to medical practitioners, and to midwives and nurses, and directed that they should be communicated to British and colonial medical and nursing journals. We have consequently received from the Editor of the *British Medical Journal* the appended important document addressed in its main bulk to all medical practitioners, but with a brief and earnest note to midwives and nurses appended:—

A.

AN APPEAL TO MEDICAL PRACTITIONERS TO PROMOTE THE EARLIER RECOGNITION OF UTERINE CANCER.

The attention of all medical practitioners is directed to the necessity of emphasising the curability by operation of uterine cancer in its early stages.

The adoption of a more extensive operation by the abdominal route has made it possible to deal successfully with cases hitherto regarded as inoperable, and to remove more of the pelvic cellular tissue as well as a portion of the vaginal walls; it is in these situations that recurrence is prone to develop.

---

[1] THE LANCET, Oct. 9th, 1895, p. 907.

Many patients now present themselves for examination and treatment when the disease is considerably advanced, and it is hoped that by a widespread and accurate knowlege of the early signs and symptoms the number of such patients will gradually diminish.

Special attention is directed to the following:—

1. Cancer of the uterus is at first a local disease.
2. Cancer of the uterus *is often* a curable disease.
3. Operation is the only satisfactory method of treatment.
4. The earlier the disease is recognised the more hopeful are the prospects of treatment.
5. The risk of operation in early cases is slight and the chance of permanent cure is good.
6. The recognition of early cancer is not usually difficult, *and the disease should not be overlooked* by the medical attendant.
7. A medical practitioner who fails to make a physical examination of a patient exhibiting any of the symptoms of uterine cancer incurs grave responsibility.
8. Treatment of symptoms without a physical examination is unjustifiable.
9. Early cancerous ulcers should not be treated with caustic; their appearance becomes masked, and valuable time is lost.
10. It is an error to wait and observe in order to arrive at a diagnosis.
11. In doubtful cases a diagnosis must and can be made in a few days.
12. To examine, to diagnose, and then to treat, should be the rule in all cases.

Symptomatology.

Uterine cancer is at first a painless disease which does not affect the general nutrition.

The early symptoms of cancer are: Irregular bleeding of any description, even if there be only traces; bleeding post coitum; and watery, blood-tinged discharge. There may be no loss of strength or wasting, nor any condition to alarm the patient. Pain, wasting, profuse bleeding, and foul discharge indicate advanced disease.

As the majority of cases occur between the fortieth and fiftieth year the symptoms are too often regarded by the patient as due to "change of life." The medical attendant should not accept this assumption until he is satisfied that cancer does not exist.

Bleeding, however slight, occurring after the menopause, should give rise to suspicion that cancer is present.

Examination.

If a patient with any of the above symptoms comes for advice, a careful visual and bimanual examination must be made before any treatment is recommended.

[illegible] ponement until the hæmorrhage has ceased.

It is most important to observe rigid aseptic precautions in all manipulations.

In the examination, the condition of the vaginal portion of the cervix and of the cervical canal should be carefully noted.

In the early stages new growth may be found on the surface of the vaginal portion of the cervix, in the lining of the cervical canal, or in the substance of the cervix. Any prominence on the surface of the vaginal portion or any ulceration—i.e., a definite loss of substance—should at once arouse suspicion. A nodule or nodules, hard, inelastic, or irregular in outline, felt in the substance of the cervix suggest the presence of cancer. If the whole cervix be affected the relative hardness as compared with the soft elastic body is pronounced.

The detection of high-lying cervical cancers and cancers of the body of the uterus is only possible after curettage or digital exploration.

The signs common to the early stages of cancer of the cervix uteri are:—

(1) The definite occurrence of new growth on the surface of the vaginal portion of the cervix, in the lining of the cervical canal, or in the substance of the cervix;
(2) Friability;
(3) Bleeding on manipulation.

(1) The definite occurrence of new growth on the portio vaginalis or in the cervical canal cannot fail to arouse suspicion. When, however, thickening of one lip or a portion of one lip of the cervix exists, the nature of the growth is difficult to determine if the mucous covering be still intact. It is then necessary to remove a portion of the affected tissue and examine it under the microscope.

(2) Friability is a sign of the greatest importance, and may be tested by the finger-nail, curette, uterine sound, or an ordinary long probe. Degrees of friability exist in early cases, depending upon the amount of interstitial tissue contained in the growth.

(3) The occurrence of free bleeding after the slightest manipulation *is, when combined with friability*, a valuable diagnostic aid.

Forms of Uterine Cancer.

Vaginal portion of the cervix.

(1) *Infiltrating type.*—In this type, one lip, or a portion thereof, or even the entire vaginal portion of the cervix, is infiltrated with cancerous growth. Ulceration occurs early from the surface inwards, or necrosis may begin in the centre, and opening on the surface, lead to the formation of a deep ulcer, with undermined edges. The growth is somewhat hard in consistence, but is still friable if tested with the probe, curette, or finger nail.

(2) *Papillomatous or polypoid type.*—This includes the so-called cauliflower excrescence, and is characterised by the growth from the margin of the os externum of a rounded or flattened tumour, varying in size, which may or may not have a definite stalk. It has a papillary surface, bleeds readily, and is very friable. More rarely it resembles a bunch of soft papillomata. Portions of the growth, pale red or greyish yellow in colour, are easily detachable on examination.

(3) *Superficial flattened type.*—This is characterised by a flattened growth on the vaginal portion which tends to spread over its surface. It is prone to early ulceration and is frequently seen clinically as an ulcer. The lip or portion affected is thickened. The ulcer has a sharply defined, raised edge, indented at places, yellowish grey, finely granular surface, a moderate amount of loss of substance, and an infiltrated base. It bleeds readily on touch and the amount of hæmorrhage is entirely out of proportion to the amount of injury inflicted. The finger-nail can detach small pieces from its surface.

Cervical Canal.

(1) *Superficial type.*—The inner surface of the cervical canal is lined by an irregular papillary growth which at first attacks the substance of the cervix superficially. As the growth increases portions of it may protrude through the external orifice of the cervical canal. When ulceration occurs the superficial portion of the growth is shed, with consequent hollowing out of the cervical canal, whilst the remainder of the periphery of the cervix is more or less thickened by infiltration. Where the external os uteri is narrow the process may be hidden, or patency of the os uteri may be produced by destruction of its margin, whilst in uteri where the os is already wide a crater-like cavity is formed.

(2) *Infiltrating type.*—The cancerous infiltration proceeds from the mucous membrane deep into the tissues of the cervix, and thus the whole cervix becomes thickened and enlarged, or the enlargement and infiltration may be limited to one or more portions of the cervical walls. Necrosis may commence on the mucous surface, or in the centre of the infiltrated area and may lead to extensive destruction of the cervical tissues.

Probably the majority of cancer cases which are overlooked are examples of disease affecting the lining of the cervical canal or the tissues of the wall of the cervix.

Cancer beginning in the cervical canal is not difficult to detect where the os uteri is dilated as in many multiparæ. The finger passed into the cervical canal feels irregular elevations or nodules from which portions may be removed. Free hæmorrhage follows this manipulation. Difficulty arises on this question of salaries the Commissioners are apparently throwing overboard the memorandum of their medical Commissioner on the subject, and that they treat an expression of his opinion that highly qualified medical men are lost to dispensary service in Ireland on account of its insufficient emoluments, as if this were a matter of but trivial importance to the public service and to the patients concerned. We note, however, that the Commissioners appear to recommend the fixing of salaries on a uniform principle and the provision of substitutes during a fixed holiday. They also say:

> The appointment and control of surgeons and physicians in the county infirmary, fever hospitals, district and cottage hospitals, and of the dispensary medical officers, by the Pu[illegible] unify the medical service of the county. authority of a county medical superinten[illegible] viso the district medical officers of health, will lead to close coöperation between the medical and public health services.

In giving a brief outline of the recommendations of the Majority of the Commission we have omitted detailed reference to general questions of poor-relief. We may mention, however, that with regard to children, extension of boarding-out is recommended with suitable inspection, and that the policy recommended for England and Wales is otherwise adhered to. We have also refrained from citing what we may call the narrative portions of the report, so far as they relate to workhouse conditions, although these may be perused with considerable interest. They appear to prove that in Ireland institutional conditions, varying under different degrees of good or bad management, are frequently very bad indeed. They may be no worse than those to which the inmates have been accustomed in their own homes, but in Ireland, even more than with us, it is desirable that this standard should often be disregarded. Public Assistance Authorities and Committees and Voluntary Aid Committees will have before them, if and when they are instituted, a prospect of useful and very arduous work if they desire to perform their functions effectively, and in Ireland, as in England, new conditions and higher standards may be found to impose considerable strain upon those who voluntarily devote themselves to public service.

The Minority Report, occupying three pages only, bases its disapproval of the Majority Report principally on the non-elective character of the Public Assistance Authorities and Committees, combined with the influence assigned to Voluntary Aid Committees, and upon features in the report which, in the opinion of the signatories, tend to perpetuate Poor-law characteristics in distribution of relief. They also refer to the departures of the Commission from the recommendation of the Viceregal Commission as "momentous" and as not justified either by the limited time at its disposal for the investigation of Irish conditions or by the evidence before it. They deprecate any hasty legislation on the lines of the report. With regard to medical matters, they express dissent from the recommendations of the Majority, and claim the support of the medical member of the Irish Local Government Board for their views, but do not refer to the proposal with regard to a State medical service advocated by the Viceregal Commission, and their criticism is not quite easy to follow owing to the small space which they have been able to devote to it. In conclusion they say: "Ireland even more than England or Scotland appears to us to be ready for the policy of 'break up the Poor-law and abolish the workhouse.' In our judgment any attempt to set up a new Poor-law and a new Poor-law authority under whatever name would be a repetition of the mistake of 1838. We have already indicated tentatively in our Report on England and Wales the way in which the various proposals with regard to the treatment of the infants, the children, the sick, the mentally defective, the infirm, the aged, and the unemployed able-bodied respectively, to which our investigations have led us, might be made applicable to Ireland. To these proposals and tentative suggestions we need, therefore, now do no more than refer."

CONVALESCENT HOMES ASSOCIATION.—The fourth annual meeting of this association will be held in the committee room at 32, Sackville-street, London, W., on May 20th, at 4.30 P.M. Sir William S. Church, Bart., K.C.B., will take the chair. The report for the year 1908 will be submitted and the object and work of the association will be explained.

SANITATION IN INDIA.

IV.[1]—JAILS.

Bombay.

THE report for the Bombay Jail Department for the year 1907 is contributed by Mr. H. N. Alexander, the Inspector-General of Prisons, Bombay Presidency. We are first presented with the usual statistical results, from which it is seen that the total population of all classes of prisoners confined in the prisons, subsidiary jails, lock-ups, and civil jails during the year 1907 has been 87,250, against 92,408 in 1906, the daily average population having been 8854, showing a decrease of 503 over the figures of the latter year. Whilst there is this general diminution, certain jails show a marked increase, such as Karachi, Hyderabad, and Sukkur, chiefly due to the great activity shown by the police in prosecuting bad characters under Chapter VIII. of the Criminal Procedure Code.

With respect to the disposal of convicts, we see that there was considerable overcrowding in Sind prisons during certain portions of the year, and this resulted in an appreciable increase in punishments. Thus at the Central Prison, Hyderabad, the increase in punishments did not begin to show itself until the prison became uncomfortably overcrowded, and then every class of offence rose rapidly. Assaults became somewhat frequent and the superintendent found considerable trouble in exacting tasks, and many penalties for these classes of offences had to be inflicted. The effect of this overcrowding was doubtless aggravated by the natural propensities of the Sindhi prisoners. The latter always give a good deal of trouble when they first arrive at a prison in the Presidency proper. Lazy by nature, they try every dodge, and take much punishment before they settle down to work; thus, of the 13 floggings for violent assaults recorded, ten were inflicted on Sindhi prisoners.

Coming now to the vital statistics for the Bombay jails, the total number of deaths for 1907 was 180, or a ratio of deaths per 1000 of 20·3, as contrasted with 204 and 21·8 per 1000 for 1906. As regards the chief diseases responsible for the sickness and mortality, dysentery, respiratory disorders, and malaria were the affections not showing a decline over the corresponding numbers of the previous year. Pneumonia was rather prevalent in some of the jails; thus in Sind gang there were 54 attacks, with 13 deaths. Precautionary measures here were at once adopted, which resulted in the mitigation of the severity of the disease, but not in its eradication. The pneumonia here was doubtless due in some measure to the great and rapid atmospherical changes. Again, in the Hyderabad Central Prison, out of 33 deaths 18 were due to pneumonia The medical officer writes: "There was overcrowding from May to the end of the year, and for some months cases of respiratory diseases with fevers were very numerous. Most of them were mild, but a few of them went on to pneumonia, of which disease there were 18 deaths during the year." In the Dhulia Prison the Inspector-General remarks on the part played by an indifferent water-supply on the amount of sickness. All the water is boiled, but it is not at all certain that the prisoners only drink the water that had been boiled. As the municipality is now constructing filter beds, an improvement in the water-supply may be expected in the future. There were no cases of cholera during 1907 in the Bombay jails. The following measures were adopted during the year under report with a view to improve the health of the prisoners. To relieve overcrowding in barracks tents were erected; the prisoners were given an allowance of wheat and rice in lieu of *bâju* and *jowâri*; weakly prisoners and convalescents had extra rations; working prisoners in the Deccan gang had two ounces of extra flour; quinine was issued as a prophylactic; potatoes and onions were given in place of green vegetables; extra warm clothing was issued when necessary; and lastly, Professor Haffkine's prophylactic serum was inoculated. With regard to the latter precaution there were eight cases of plague, with three deaths.

The two new prisons at Sukkur and Karachi are likely to prove healthy. At Sukkur Captain Murison, I.M.S., the superintendent, remarks on the total absence of cases of heat stroke during the year, as contrasted with the admission [illegible] l has proved decidedly [illegible] which is now disused.

---

[1] Nos. I., II., and III. were published in THE LANCET of April 10th (p. 1067), and 24th (p. 1199), and May 1st, 1909 (p. 1269), respectively.

Central Provinces.

Major W. B. Lane, I.M.S., the Inspector-General of Prisons, furnishes the report for those of the Central Provinces. Here, again, it is satisfactory to find that the number of prisoners, which has been steadily decreasing since the year 1903, continues to show a further fall in 1907, and this decrease also embraces that in the number of juvenile prisoners under 16 years of age. But although there was this general decrease, it was found that there was an increase in the number of persons admitted who were in Government employ—namely, from 196 in 1906 to 235 in 1907. Another point observable is the rise in the number of short sentences not exceeding three months. It is very difficult to make life penal for those undergoing very short sentences; they cannot be taught any trade, cells are not available for the grinding of grain, and they are nearly always put to work in the garden, which is not penal; having once been in jail the boundary line is passed and imprisonment becomes no deterrent after such an experience. There was a great increase in this respect in the Raipur central jail, there being 223 admissions in 1907, as against 142 in 1906. Major Lane urges that the punishment in these cases should be more real, and suggests certain lines on which this could be effected.

An important measure for the separation of habitual prisoners sentenced to six months and over has been sanctioned; under this sanction these prisoners are now to be transferred to central jails. Hitherto it has been the practice to transfer long-term prisoners from the central jail to the district jail nearest their homes two months before [illegible] placed. Major Lane has reduced this period and now all such prisoners are transferred not more than a fortnight before their release, and are also as far as possible separated from the other casual offenders in the district jail. Thus contact between hardened habitual criminals and the comparatively harmless class of casual offender will be in a great degree prevented. But not only is the future of the casual offenders looked after, but the Inspector-General has interested himself in that of the habitual. This problem of providing for habitual prisoners after their release is a difficult one. In Nagpur several such prisoners were given employment in the secretarial press. The results, however, so far are not encouraging, only one man out of the six so employed having remained in this employment, but, as the Inspector-General remarks, this "is something gained."

Coming now to the vital statistics of the jails for the Central Provinces, the ratio per 1000 of daily average sick showed a marked fall, but there was a large rise in the death-rate, which rose from 13 to 18 per 1000 in respect of convicts, and from 20 to 29 in respect of under trial prisoners. However, with respect to this, it must be remembered that this death-rate of the previous year was exceptionally low, and less than that returned by the jails of any other province, whilst the death-rate of 18 per 1000 in 1907 is still quite low, and compares favourably with that of any place or any class of people in India. Out of 63 deaths 19 occurred in Raipur alone, dysentery accounting for seven or half the total number of deaths from this cause in the jails of the whole province. The occurrence of the dysentery does not receive any explanation as to whether it was due to the exceptionally bad health of the admitted prisoners that was present, or whether it was due to any cause or defect in the conditions of sanitation or dieting in the jail. In the Amraoti central jail, again, five out of the seven deaths reported were due to dysentery. With respect to this disease as it presented itself as a whole in the jails, we see there was a fall in the admissions from 119 in 1906 to 103 in 1907, although the number of deaths rose from seven to 14. There was only one case of plague, and no case of cholera. Malarial fever showed a decrease of 146 cases from 641 cases in 1906 to 495 in 1907. Quinine was issued as a prophylactic at some jails, but the Inspector-General can draw no deductions as to its efficacy or otherwise. Captain P. Prentice, of the Balaghat district, thinks with regard to prevention he has reduced the number of cases by rubbing the exposed parts of prisoners' bodies with a mixture of tilli and kerosene oil. Incidentally with respect to the admissions of malaria, Captain W. H. Kenrick, in his report of the Saugor jail, made the important observation that quite 50 per cent. of the cases said to be malaria were really not malaria at all, but a form of spirillosis caused by a spirochæte transmitted most probably by the bite of a tick or bed-bug. He considers that the majority of cases of malaria occurring in jails are really cases of this nature and not malaria, quinine having no effect upon them; they recover just as soon untreated, whereas the genuine cases of malaria are very few. Microscopic examination is necessary to distinguish the two diseases. In concluding his interesting report Major Lane gives well-deserved commendation to, and mentions with praise the names of, several of the jail superintendents. We are glad to see this, as such mention always stimulates to good work.

Bengal.

Lieutenant-Colonel W. J. Buchanan, the Inspector-General of Prisons, Bengal, submits the report for this province. We are extremely glad to note that the wise proposition of this energetic officer with respect to the separate and special treatment of juvenile prisoners has been definitely agreed upon by the Government of Bengal. Last year Colonel Buchanan strongly recommended a scheme for making better provision for this separate and special treatment. He rightly was of strong opinion that any attempt to reform prisoners could only expect a successful result if such prisoners were obtained young, and when so obtained were treated separately from the adult prisoners, for if at their impressionable age they came into contact with the latter, they would be apt to deteriorate rapidly and to learn all the worst tricks and vices of adult criminals. He proposed, therefore, that a juvenile jail in Calcutta should be established, and asked that the premises now used as the Alipore Reformatory School should be restored to the jail department to which they formerly belonged. In commenting last year on this proposition we held "that this common-sense reform was eminently desirable, and trusted that the Government would fall in with the wise and humane views of this able administrator." The Inspector-General is to be congratulated on the fact that the Government of Bengal has acceded to his views. The actual transfer had not yet taken place at the time of the writing of his report, but it had been definitely agreed upon.

Respecting the statistics for admission for 1907, the number admitted and discharged, and the daily average number of prisoners, have decreased as compared with the previous year. The various statements in the report detail the number of convicted prisoners and their disposal during the year, the number of transportation convicts, the particulars of the religion, age, state of education, and previous occupation of the convicts, also the number of female convicts, and the nature and length of sentence of convicts admitted during the year amongst other particulars. A wise proceeding—namely, that of the removal daily or more than once a week of convicted prisoners from certain subsidiary jails to the district jails at headquarters, has been sanctioned. This, although throwing much additional work on the police department in providing escorts, has been of great use to this department in keeping down the numbers in the subsidiary jails, many of which, in spite of this more frequent removal of convicts, are still often found to be inadequate to accommodate the number of prisoners awaiting or under trial. Considerable sums of money have also been expended on the reconstruction and enlargement of the subsidiary jails in many districts, as many of the latter built 30 or 40 years ago were found of quite inadequate accommodation, in spite of the above system of immediately transferring convicted prisoners to the district jail at headquarters.

Colonel Buchanan last year urgently proposed an increase in the pay of all warders, a slight increase in the total number of warders in each jail, an improvement in the pay and status of the reserve head warders in central and first- and second-class district jails, a [illegible] warders with the local allowan[illegible] extension of privileges given to the police and Salt Department officers. These recommendations are now under the consideration of Government, and we trust, with Colonel

Buchanan, that a favourable reply may be given to his beneficent recommendations, for the warders, who are drawn from the same class as the police, keenly feel that they by no means receive equal treatment with them, and hence there is found to be a yearly increasing difficulty in recruiting a good class of men, together with an increased number of retirements and desertions. Colonel Buchanan rightly holds the most pressing jail reform to lie in the necessity of "not only making provision for increased pay, but also for extending to this hard-worked body of men similar privileges as regards pension and sick leave to those enjoyed by the police department." Surely a wiser recommendation was never made.

Several other points are noticed in this excellent report before we come to the facts concerning the sickness and mortality in the jails. For the year 1907 the daily average sick was 523·80, as against 576·44 in 1906, or a ratio per 1000 of 34·2, as contrasted with 36·5, the mortality-rate being respectively 17·5 and 23·7 per 1000. With respect to the chief diseases encountered, only five cases of cholera with three deaths occurred, against 21 and 15 respectively in 1906. Dysentery likewise showed a decrease, there having been 1984 admissions with 43 deaths, compared with 2738 and 83 in 1906. The death-rate per 1000 from this disease was 3·0, against 5·9 in the previous year. Bowel complaints always figure very largely in the sick-rate and mortality of prisoners in jails, but the rate for 1907 has marvellously decreased in the Bengal jails. Thus, in the five years 1875–79 the death-rate was 26 per 1000; this year it is far lower, only 3·2. The deaths this year have been about half the previous lowest record. This low death-rate has been almost universal in the Province.

Captain W. O. H. Forster, I.M.S., has instituted a special inquiry into the causation of jail dysentery, and has shown in his interim report that the dysentery is most commonly due to the bacillus of Shiga, amœbæ having been found very seldom in primary attacks, but more frequently in chronic cases. He shows it not to be spread by dust, water, food-supply, suctorial insects, or soil infection, nor does the infection, as far as could be traced, cling to wards or buildings. All the available evidence points to the spread by *case-to-case infection and by convalescents as bacilli carriers.* The extra-corporeal stages of dysentery were found to be extremely short. The sun's rays killed the bacillus in two hours, whilst bacilli died within three days in blankets stowed away in almirahs. The greatest incidence occurred one month after the rainfall curve; the minimum incidence corresponded with the dry hot months. Most of the cases occurred in recent arrivals from outside, or among convalescent gangs. Cases of dysentery due to Shiga's bacillus were found liable to assume a chronic or relapsing course, whilst convalescents were very dangerous as carriers and spreaders of the disease. As regards prophylaxis, therefore, we must exercise due attention to sanitation, the early admission and treatment of cases, and especially the detention in hospital till they become "absolutely well for at least a fortnight," together with the segregation of convalescents for at least a month after their discharge from hospital. Captain Forster also recommends the preliminary treatment of all new-comers during their necessary detention in the quarantine yards by salines and perchloride of mercury, inasmuch as a large proportion of jail cases occur amongst newly admitted prisoners. This preliminary treatment has proved very satisfactory in the Midnapore Jail. This hard-working officer has also introduced, and largely used, a method of vaccine-therapy which has been very successful, several most remarkable recoveries having been personally noted by the Inspector-General, who strongly advocates its use in other jails. Midnapore Jail is notorious for its unhealthiness, so that the efforts of Captain Forster are highly to be commended and reflect the greatest credit on this officer.

Lastly, a few words may be said on the subject of the state of malaria in Bengal. There were 4928 cases, with 16 deaths, in 1907, as compared with 4853, and 18 in 1906. The death-rate from these fevers is the lowest since 1880. Anti-malarial and anti-mosquito operations are now carried out in all the Bengal jails, and Colonel Buchanan believes that the majority of the cases arise from infection by newly arrived prisoners. Quinine as a prophylactic is issued in all the jails, in the majority of cases 15 grains on two successive days being given to all prisoners from July to the end of November. An important point is that although thousands of pounds of quinine have been used for ten years in large doses in the jails, there has not been a single case of blackwater fever, showing that quinine *alone* will not cause the disease. The report closes with an account of the movements of the various medical officers, and in it is mentioned the fact that Lieutenant-Colonel H. J. Dyson, whose premature death was so great a loss to the service, stuck to his jail practically till the last. It is always a pleasure to review any of Colonel Buchanan's work, which he so ungrudgingly gives to the Government he serves so well.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

The Port of Manchester.—Mr. W. F. Dearden in his current annual report enters into some detail as regards the important matter of food inspection, a subject which has acquired an added interest recently in consequence of the operations of the Public Health (Regulations as to Food) Act, 1907. A useful chart is furnished showing for each of the principal ports during 1907 the value of food imports compared with the value of total imports from abroad. The three chief ports as regards food imports are in order of magnitude London, Liverpool, and Hull, Manchester coming fourth as regards total imports but not as regards food imports alone. In connexion with the inspection of fresh meat it is of interest to note that one animal slaughtered shortly after landing on account of illness was found to be suffering from Texas fever. Mr. Dearden states that the inspections at the Foreign Animals Wharf are rendered difficult by virtue of the fact that slaughtering takes place at very irregular hours, notwithstanding the fact that the Manchester corporation has laid it down that no slaughtering shall be permitted on the premises in question after 6 P.M. on Saturday until 2 A.M. on Monday. Apparently the importers commence operations at any time convenient to themselves, whether on Saturday, Sunday, or other days Consequently the inspector is often absent during a portion of the time when slaughtering is taking place. This seems an eminently unsatisfactory state of affairs and not one which is likely to guarantee wholesome meat reaching the consumer. As regards grain, 694 tons were seized during 1908. Very little tinned fruit pulp was dealt with during the year as compared with 1907, but Mr. Dearden is unable to say whether this food may not be reaching Manchester *viâ* the railroad in consequence of the vigorous action taken against it in 1907. Considerable quantities of tinned meats were imported, but owing to the scarcity of American cattle the American exports consisted chiefly of meats which had been packed prior to 1906, but which had been examined by sample by the American authorities and found to be sterile. A very good feeling seems to obtain in the Port of Manchester between the food inspectors and the importers and a large number of tins are surrendered voluntarily. As we pointed out in THE LANCET of April 24th, a large number of pigs' tongues, packed in barrels and preserved in "patent pickle," was imported, and in consequence of decomposition having been set up in 49 of the barrels the contents of them were seized. The preserving fluid was found crowded with bacteria and the interiors of the tongues were decomposed. The preserving liquid consisted for the most part of sodium chloride and boric acid, there being in one instance examined 66·56 grains of boric acid per pound of preserving liquor. The ends of the barrels were bulging and when pierced a turbid liquid spurted therefrom. Moreover, the tongues were trimmed of every particle of lymphatic glands, and it is probable that the Local Government Board will be asked to prohibit the importation of tongues so treated. Tinned peas were also condemned in large quantities owing to the excessive amount of copper with which they were coloured Condensed milk is introduced by way of Manchester in substantial amounts, a considerable proportion which comes *viâ* Rouen being prepared from unskimmed milk, and the remainder which comes *viâ* Rotterdam being prepared from what is described as "machine skimmed milk." Only one consignment, 20 per cent. of which tins were found to be "blown," was condemned. In connexion with this important question of tinned milk Mr. Dearden states that all tins of sweetened condensed milk contain micro-organisms to a greater or less degree; the contents of a large number exhibit the *enteritidis* reaction and the presence of the bacillus coli communis has certainly been demonstrated.

Bath Urban District.— [illegible] 51,844, and in 1901 it [illegible] it was estimated at betw [illegible] Symons, the medical officer of health, furnishes in his report the figures relative to the Bath patients who were discharged from Winsley Sanatorium during the three years 1905 to 1907, and we are glad to see that the after-results have been kept in the manner recommended by Dr. H. T. Bulstrode in his report upon sanatoriums—that is to say, the figures for each year are kept separately and in such a fashion that the patients treated in any one year can be followed through successive years. In 1905 there were six Bath patients discharged from Winsley, and of these there were in January, 1908, two alive, one of whom was at full work. Of six discharged in 1906 there were four alive, three of whom were working in 1908. Under the Midwives Act of 1902 medical aid was called for in 82 cases, and Dr. Symons reports that the qualified midwives who are able to recognise danger call in medical aid in a large proportion of their cases, and he adds that the returns indicate that the infantile mortality in connexion with confinements attended by midwives was no greater than among those attended by medical men. There were 79 deaths among the infants of residents during 1908, and of these 20 took place during the first week and 35 during the first four weeks, the principal cause being premature birth. Dr. Symons thinks that the prevention of these deaths is a matter more for the Babies' Welcome Society than for the usual routine work, since it has been found a very difficult matter to rear immature infants.

Ilkley Urban District.—Dr. Augustus H Bampton has recommended that the sewer ventilators in the streets of this town should be covered over since he considers that surface ventilators can be dispensed with without danger. There are, he states, no surface ventilators in Bath, Blackpool, Bournemouth, Hastings, Eastbourne, and Scarborough, but he does not tells us which, if any, method of ventilation is adopted in the place of surface ventilators. It is quite true, as Dr. Bampton states, that Bristol has no ventilators whatever to the sewers, and it is impossible to demonstrate that the health of the city suffers in any particular thereby. Certainly the whole question of the ventilation of sewers is in need of elucidation, and it would be a useful course [illegible] the Local [illegible] with the w [illegible] se of interce [illegible] Burns last w [illegible] istics for Ilkley for 1908 do not suggest that the defective sewers have influenced the death-rate in any undue degree. The general death-rate for 1908 was 8·4 per 1000, the zymotic death-rate 0·28 per 1000, and the infantile mortality 45·7 per 1000 births.

Metropolitan Borough of Chelsea.—The Chelsea borough [illegible] lopt the Notification of Births [illegible] committee not being satisfied [illegible] workable. There is, however, a lady sanitary inspector in the borough who is doing good work, and in connexion with the subject of illegitimate births she reports that as the majority of the mothers of such children are obliged to go to work they have either to put their children out to nurse entirely or leave them in [illegible] g working hours. The usual [illegible] boarded out is from 5s. to 6s [illegible] minding," exclusive of food, the average charge is 4*d*. The result is that the majority of illegitimate infants are brought up by hand and bottle-fed. Of the total number of scarlet fever cases which were admitted from Chelsea into the [illegible] there were 18 who [illegible] suffering from scarlet [illegible] an average stay of 23 [illegible] stration of the hospitals that none of these children contracted the disease. Dr. Louis C. Parkes furnishes in his report a table showing the [illegible] scarlet fever, diphtheria, and [illegible] removed from Chelsea to th [illegible] hospitals since 1891, and in 1908 the several percentages amounted to 95, 91, and 71.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8995 births and 4462 deaths were registered during the week ending May 8th. The annual rate of mortality in these towns, which had been 17·1, 15·8, and 14·5 per 1000 in the three preceding weeks, further declined to 14·1 in the week under notice. During the first five weeks of the current quarter the death-rate has averaged 15·7 per 1000, the rate in London during the same period being 15·3. The lowest recorded annual death-rates in these towns last week were 6·5 in Hornsey, 6·9 in Reading, 7·2 in Willesden, and 8·0 in Rotherham; the rates in the other towns ranged upwards, however, to 20·6 in Stockport, 20·8 in St. Helens, 21·2 in Hanley, and 22·4 in Wolverhampton. In London the recorded death-rate during the week was equal to 14·1 per 1000. The 4462 deaths from all causes in the 76 towns last week showed a decline of 107 from the number in the previous week, and included 445 which were referred to the principal epidemic diseases, against 583, 517, and 462 in the three preceding weeks; of these 445 deaths, 198 resulted from measles, 109 from whooping-cough, 46 from diphtheria, 43 from scarlet fever, 42 from diarrhœa, and seven from "fever" (principally enteric), but not any from small-pox. The 445 deaths from these epidemic diseases in the week under notice were equal to an annual rate of 1·4 per 1000, against 1·9, 1·6, and 1·5 in the three preceding weeks. No death from any of these epidemic diseases was registered last week in Brighton, Norwich, Birkenhead, Northampton, or in nine other smaller towns; the annual death-rates therefrom ranged upwards, however, to 3·2 in Swansea, 3·6 in Warrington, 3·7 in Salford, 4·4 in St. Helens, 4·5 in Middlesbrough, and 5·2 in Wigan. The fatal cases of measles, which had declined from 438 to 225 in the seven preceding weeks, further fell last week to 198, but caused death-rates ranging upwards to 1·9 in Salford, 2·0 in Wolverhampton and in Stockton-on-Tees, 2·2 in St. Helens and in Warrington, and 4·6 in Wigan. The deaths from whooping-cough, which had been 131 and 113 in the two preceding weeks, further decreased to 109 in the week under notice, the highest death-rates from this disease being 1·1 in St. Helens, 1·9 in Tynemouth, 2·1 in Swansea, and 3·5 in Middlesbrough The fatal cases of diphtheria, which had been 47, 48, and 37 in the three preceding weeks, rose again last week to 46, of which 15 were registered in London and its suburban districts, four in Manchester, and three in Portsmouth. The 43 deaths from scarlet fever exceeded the numbers in other recent weeks, and included 14 in London and its suburban districts, four in Liverpool, four in Manchester, and three in Salford. The 42 fatal cases of diarrhœa also showed a slight excess over recent weekly numbers, while the deaths from "fever," which had been 13 in each of the two preceding weeks, declined to seven in the week under notice, and were fewer than the number in any previous week of the year. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had decreased from 2373 to 2181 in the nine preceding weeks, had further fallen to 2175 at the end of last week; 309 new cases were admitted during the week, against 244, 265, and 305 in the three preceding weeks. The registered deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 341, 294, and 232 in the three preceding weeks, further declined to 212 in the week under notice, and were 58 below the corrected average number in the corresponding week of the five years 1904-08. The deaths in London referred directly to influenza, which had been 45 and 32 in the two preceding weeks, fell last week to 10, but were equal to the corrected average number. The causes of 40, or 0·9 per cent., of the deaths registered in the 76 towns during the week were not certified either by a registered medical practitioner or by a coroner. The causes of all the deaths registered during the week were duly certified in London, Manchester, Leeds, Bristol, West Ham, and in 50 other smaller towns; the 40 uncertified causes of death included nine in Liverpool, four in Birmingham, three in Gateshead, and two each in Sheffield, Leicester, Bolton, Sunderland, Preston, and Rochdale.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 18·4, 17·4, and 16·9 per 1000 in the three preceding weeks, further declined to 16·2 in the week ending May 8th. During the first five weeks of the current quarter the death-rate in these towns averaged 17·3 per 1000, and exceeded by 1·6 per 1000 the mean rate during the same period in the 76 large English towns. Among the eight Scotch towns the death-rates during the week under notice ranged from 12·5 in Paisley and 13·0 in Greenock, to 19·4 in Dundee and 20·6 in Perth. The 577 deaths from all causes registered in the eight towns last week showed a further decline of 28 from the numbers in recent weeks, and included 78 which were referred to the principal epidemic diseases, against 86 and 93 in the two preceding weeks; of these 78 deaths, 41 resulted from whooping-cough, 17 from diarrhœa, eight from measles, eight from scarlet fever, two from diphtheria, and two from cerebro-spinal meningitis, but not any from small-pox or from enteric fever. These 78 deaths were equal to an annual rate of 2·2 per 1000, or 0·8 more than the mean rate last week from the principal epidemic diseases in the 76 English towns. The fatal cases of whooping-cough in the eight Scotch towns, which had been 46 and 55 in the two preceding weeks, declined again to 41 in the week under notice, and included 26 in Glasgow, eight in Edinburgh, and four in Aberdeen. The deaths from diarrhœa, which had risen from 13 to 21 in the four preceding weeks, declined again last week to 17, of which eight occurred in Glasgow, three in Aberdeen, and two each in Edinburgh and Dundee. The fatal cases of measles, which had been six and two in the two preceding weeks, rose again to eight last week, and included five in Paisley and two in Aberdeen. The eight deaths from scarlet fever exceeded the numbers in other recent weeks, and included six in Glasgow, where the two fatal cases of cerebro-spinal meningitis also were registered. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 135, 118, and 99 in the three preceding weeks, further fell to 88 in the week under notice, and were 31 fewer than the number returned in the corresponding week of last year. The causes of 17, or 3 per cent., of the deaths registered in the eight towns last week were not certified; in the 76 English towns the proportion of uncertified causes of death in the same week did not exceed 0·9 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been 27·7, 24·5, and 22·0 per 1000 in the three preceding weeks, further fell to 18·8 in the week ending May 8th. During the first five weeks of the current quarter the death-rate averaged 23·7 per 1000, whereas the mean rate during the same period did not exceed 15·3 in London and 17·1 in Edinburgh. The 144 deaths of Dublin residents from all causes during the week under notice showed a decline of 24 from the number in the preceding week, and included eight which were referred to the principal epidemic diseases, against 21, 12, and 16 in the three preceding weeks. These eight deaths were equal to an annual rate of 1·0 per 1000, the death-rate from the principal epidemic diseases in the same week being equal to 1·6 both in London and in Edinburgh. Of the eight deaths from these epidemic diseases in Dublin last week, four resulted from whooping-cough, two from measles, and two from diarrhœa, but not any from small-pox, scarlet fever, diphtheria, or "fever." The 144 deaths registered during the week included 26 of infants under one year of age and 34 of persons aged upwards of 60 years, the corresponding numbers in the previous week having been 31 and 53 respectively. Six inquest cases and three deaths from violence were registered last week, and 49, or 34 per cent., of the deaths occurred in public institutions. The causes of three, or 0·2 per cent., of the deaths in Dublin during the week were not certified either by a registered medical practitioner or by a coroner; in London the causes of all the 1304 registered deaths were certified, while in Edinburgh the proportion of uncertified deaths was 4·5 per cent.

THE SERVICES.

THE NEW DIRECTOR-GENERAL OF THE INDIAN MEDICAL SERVICE.

Lieutenant-Colonel Charles Pardey Lukis, principal of the Medical College, Calcutta, has been selected to succeed Sir Gerald Bomford, Director-General, Indian Medical Service, who is proceeding home preparatory to retirement. Colonel Lukis entered the service in 1880, and was with the field forces engaged in Wazirstan in 1881 and Zhob Valley in 1884. He entered the Civil Department in 1886 and was stationed in the United Provinces until 1899, when he became Civil Surgeon of Simla. He accompanied Lord Curzon to the Persian Gulf in 1903, and became honorary surgeon to the Viceroy in 1905.

ROYAL NAVY MEDICAL SERVICE.

In accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Fleet-Surgeon John Jenkins has been placed on the retired list at his own request (dated May 7th, 1909).

ROYAL ARMY MEDICAL CORPS.

The undermentioned Captains to be Majors (dated April 28th, 1909):—John McD. McCarthy, John Poe, Hamilton G. F. Stallard, and Ernest Brodribb.

TERRITORIAL FORCE.

Infantry.

10th (Scottish) Battalion, The King's (Liverpool Regiment): Surgeon-Lieutenant David M. Alexander resigns his commission (dated March 11th, 1909).

Royal Army Medical Corps.

London Mounted Brigade Field Ambulance: The appointment of Henry Robinson to a Lieutenancy bears date April 1st, 1908, and not March 5th, 1909, as stated in the *London Gazette* of March 26th, 1909.

3rd West Lancashire Field Ambulance: Richard Coffey to be Lieutenant (dated Jan. 11th, 1909).

5th London Field Ambulance: Sidney Francis St. Jermain Steadman to be Lieutenant (dated Feb. 19th, 1909).

2nd Welsh Field Ambulance: Major Alfred William Sheen to be Lieutenant-Colonel (dated Feb. 1st, 1909).

1st London (City of London) General Hospital: Major Wilmot Parker Herringham is seconded for service with the London University Contingent, Senior Division. Officers Training Corps (dated Feb. 20th, 1909).

2nd Western General Hospital: The following announcement is substituted for that relating to Major W. Thorburn which appeared in the *London Gazette* of April 27th, 1909:—Major William Thorburn to be Lieutenant-Colonel and to be an officer whose services will be available on mobilisation (dated Feb. 28th, 1909).

Sanitary Service.—Lieutenant-Colonel John A. Jones.

For Attachment to Units other than Medical Units.—Thomas Hanson Crossfield Derham to be Lieutenant (dated Jan. 1st, 1909). Thomas Brown to be Lieutenant (dated (April 3rd, 1909).

Attached to Units other than Medical Units.—Lieutenant-Colonel C. Downing, Major Frederick V. Adams, Major Ernest W. Barnes, Major Harry T. Challis, and Major Alfred Rees.

The undermentioned officers are granted the honorary rank of Surgeon-Colonel (dated March 31st, 1908):—

Royal Field Artillery.

2nd Northumbrian Brigade: Surgeon-Lieutenant-Colonel Thomas McC. Foley.

Infantry.

6th Battalion, The Prince of Wales's (North Staffordshire Regiment): Surgeon-Lieutenant-Colonel J. Fausset.

The undermentioned officer is granted the honorary rank of Surgeon-Lieutenant-Colonel (dated March 31st, 1908):—4th Battalion, The Welsh Regiment: Surgeon-Major Evan Evans.

The undermentioned officer is granted the honorary rank of Surgeon-Major (dated March 31st, 1908):—4th Battalion, The King's Own (Royal Lancaster Regiment): Surgeon-Captain Richard J. Morris.

THE UNIVERSITY OF LONDON OFFICERS TRAINING CORPS.

The first general parade of this contingent was held at the

University of London, South Kensington, on May 12th (Presentation Day), when addresses were delivered by the Vice-Chancellor, Sir William Collins, M.P., and Lieutenant-General Sir W. H. Mackinnon, Director-General of the Territorial Force, representing the War Office.

Correspondence.

"Audi alteram partem."

THE MEDICAL TREATMENT OF LONDON SCHOOL CHILDREN.

To the Editor of THE LANCET.

SIR,—As a physician to one of our general hospitals and as an assistant physician to a special hospital in London, I write to thank you for being so public-spirited as to publish an annotation in the current number of THE LANCET on the Medical Treatment of London School Children. You say, "the idea of using the honorary services of the medical staffs in return for a grant to hospital funds seems to us monstrous." I agree with every word of your protest and am sure that it is high time that the public should be completely informed of the burden which already rests on the shoulders of the honorary medical staffs of our London hospitals. Were the facts known to the public as thoroughly as they are to you, I am quite sure this further exploitation proposed by the London County Council would never have been mooted. Your suggestion that there should be a meeting of the honorary staffs of our hospitals is excellent, but I am hopeful that your strongly worded protest will render such a step unnecessary.

I am, Sir, yours truly,
H. BATTY SHAW, M.D. Lond., F.R.C.P. Lond.
Devonshire-street, W., May 7th, 1909.

To the Editor of THE LANCET.

SIR,—I am glad to see that you are calling attention to the serious questions raised by the new Education Act. So many interests are involved that it is to be expected that no hurried decisions will be taken. I doubt if any hospital authority would act in such a matter without consulting the hospital staff, and, speaking for myself alone, I should be glad if it were found possible to call some meeting at which the staff of each London hospital should be represented.

I am, Sir, yours faithfully,
May 7th, 1909. W. P. HERRINGHAM.

To the Editor of THE LANCET.

SIR,—*A propos* of the last paragraph in your article on the above, I feel myself at liberty to state that the staff of the London Hospital discussed the matter at its last meeting and unanimously passed a resolution to the effect that it did not approve of the principle of the hospital being expected to treat such cases in return for a subsidy of public money received from the London County Council, but coupled with a rider that it was willing to meet the lay committee of the hospital to consult as to the best means by which the problem of treating these children might be met. This statement may help to set Mr. Beckett-Overy's mind at rest as to the idea that the staffs of the London hospitals are in ignorance of what is going on, but I fear it does not go very far in deciding what is to be done.

Within the limits of a letter it is impossible to discuss the problem as a whole, but one may just glance at the fundamental facts, the most obtrusive and striking of which is that if the proposal of the London County Council were attempted the special departments (ear, throat, nose, skin) of the London hospitals and even the ordinary out-patient departments would have to be enlarged to twice or even three times their present capacity to cope with the work; this simple mathematical fact alone seems to render the proposal absolutely impossible in practice. Another fact is that these "defective" children are at present being compelled to [illegible] imitation must lead to their increase.

The problem seems to me to be how to treat these children without destroying parental responsibility altogether, and with the condition of seeing that the medical profession is fairly remunerated for its services; the latter can be dealt with easily enough by several schemes, the former is doomed to oblivion, for no one seems to have sufficient moral courage nowadays even to attempt to suggest that parents have any responsibilities.

I am, Sir, yours faithfully,
Harley-street, W., May 12th, 1909. FRED. J. SMITH.

X RAYS AND RINGWORM.

To the Editor of THE LANCET.

SIR,—There appeared in the *Times* a few weeks back a letter from an Edinburgh physician suggesting that the x rays *might* have a deleterious effect on the brain cells. His remarks were directed against "Sabouraud's" method of x ray treatment for ringworm of the scalp. A "scare" has been produced chiefly by the cheaper lay press, and parents are becoming convinced that the x rays will cause their infected children to become "idiots." One might equally argue that because the profession is prescribing an occasional dose of opium our children will eventually become "morphomaniacs." The suggestion is a most pernicious one. At St. John's Hospital for Skin Diseases we have had several parents object to the x rays on account of the aforesaid letter.

Practically at all hospitals, large and small, an expert is attached who from experience knows exactly the requisite dose to produce epilation. The essence of Sabouraud's method lies in using a *low* tube, the rays of which are well known to be readily stopped by bone, even of the thickness of a child's skull. The following is a useful demonstration. I exposed the left side of a child's head, aged four years, to a low tube, the primary spark gap was three inches, the milliampèremeter registered 1, and by Benoist radiometer No. 5. A pastille was changed to the full tint in 11 minutes. A piece of lead half an inch thick and of the size of a farthing was placed on the centre of the exposed area. Examination with the screen showed the whole head opaque; the lead could not be differentiated. A Lumière plate was placed under the right side, and after the above full dose the plate was slightly fogged but no image of the lead was apparent. By the fourteenth day the left side of the head was completely bald, so that although the scalp received the maximum dose requisite to make the hair fall perfectly the brain cells, protected by the bone, must have received but little irradiation. The hair under the lead was unaffected. I am of opinion that no scalp should be treated by x rays unless the fontanelles are completely closed. The expert use of x rays for therapeutic purposes, at any rate in the treatment of ringworm, is of great value; and it is rather late in the day to suggest alarmist views, which have not a particle of evidence to support them.

I am, Sir, yours faithfully,
CHISHOLM WILLIAMS.
New Cavendish-street, W., May 8th, 1909.

EPSOM SALTS AS A POISON, AND ITS USES IN THE TREATMENT OF WARTS.

To the Editor of THE LANCET.

SIR,—I read with much interest the article by Dr. Charles Fraser on the poisonous effects of Epsom salts in your issue of April 24th, p. 1174, not only on account of the great rarity of such cases as he records, but because, as medical officer to a large Poor-law school with 600 children whose ages range from five to 16 years, his remarks were of considerable interest to me. In this school Epsom salts are largely used, as probably in most schools of this kind, and given in large doses up to half an ounce. Although I have never seen any child suffer from alarming symptoms after a dose of these salts, still I have from time to time known children complain of pain, feel sick and cold, with a pinched look about the face. One has never attached any importance to this owing to the fact that Epsom salts have always been regarded as a therapeutic agent free from danger, but after [illegible] asks one's self. Were these symptoms of [illegible] the dose taken in each of [illegible] somewhat concentrated [illegible] amongst domestic saline purgative in chronic constipation, and forms one of the pancreas incision was the normal proceeding, the drawback, however, being that a fistula sometimes was left. He showed a case where a big growth was present behind and connected with the stomach. It was a large cyst of the pancreas, but it was easily shelled out. The wound was plugged and healed within six weeks without leaving a fistula. On examination of the wall of the cyst numerous white nodules of the size of a pea were found, which proved to be sarcomatous. A year later pain began to be complained of, and then a small growth appeared in the scar and recurrence was obvious.

Operations on the Brain.

Professor VON BRAMANN of Halle described an Operation for Hydrocephalus. He trephined half a centimetre behind the coronal suture and brought the dura mater into view. He then introduced a short cannula through the commissure into the ventricle, the depth before this was reached being in children about three centimetres and in adult persons about from six to eight centimetres. When the fluid had run out the aperture in the commissure was somewhat dilated and the wound was closed. Professor von Bramann performed this operation in 22 cases, of which 13 were cases of growth, with hydrocephalus, eight were cases of genuine hydrocephalus, and one was a case of epilepsy. The effect of the operation was that the fontanelle sank, the patient's mental state improved, and the contractures and the amaurosis became better. In one case it was ascertained by post-mortem examination that the opening was still patent after seven months.

Mobilisation of Joints.

Professor KLAPP of Berlin drew the attention of the Congress to the fact that tuberculosis of the hip-joint might, in certain circumstances, get well without any impairment of the function of the joint. In cases of gonorrhœal arthritis Bier's passive congestion gave excellent results, so that incision and drainage were often unnecessary. The results were best in the acute phlegmonous form, but even in more chronic cases success might eventually be obtained provided that the technical directions were observed. As to operations for restoring mobility to ankylosed joints, the best results were obtained in the elbow-joint. It was the aim of the operation to free the existing adhesions and to avoid the formation of fresh ones. For this purpose either cartilage, or muscles, or fascia, or tendons must be interposed between the epiphyses. Professor Klapp had recently devised a new method of mobilising joints which had become ankylosed after fractures. He removed the callus but spared the surface of the joint which was then united by nails with the diaphysis from which a small piece was previously removed by the saw. Sometimes the extirpation of the shrivelled capsule was advisable.

Professor PAYR said that the condition of the capsule was the most essential point in the mobilisation of joints. Forcible breaking down of adhesions produced new cicatrisations within the capsule owing to which the joint became still more ankylosed than before. He recommended in such cases the removal of the capsule, but the ligaments should be left. According to his experiments in animals the capsule might regenerate.

While speaking on the subject of fractures, Dr. THÖLE of Hanover said that he had seen in a patient who had fallen from a horse a separation between the base of the cranium and both upper jaws, so that the face could be moved in a sagittal direction.

Professor KAUSCH of Berlin mentioned that three years ago he had implanted a piece of bone eight centimetres long, freed from periosteum, at the place of the knee-joint after resection for malignant growth. The femur was later amputated for recurrence, and on examination it was found that the periosteum of the femur and of the tibia had grown over the implanted piece. The latter had become absorbed, but new bone was formed from the periosteum and the adjoining bones. The union between the new bone which had taken the place of the implanted piece and the old bone was so close that it was impossible to differentiate the tissues. Professor Kausch added that he had in four instances implanted sterilised bone from a dead body and other material in two instances, but that in no case was a good result obtained.

Dr. WILLEMS of Gent said that in hæmarthrosis of the knee-joint he had allowed the patients to move the joint and to walk immediately after the aspiration. By early movements atrophy of the joint was avoided. He had applied this method in 12 cases of hæmarthrosis and eight cases of acute hydrarthrosis. The results were very good, no complication happened, and the duration of treatment was considerably shortened. The patients were able to begin work on an average after eight days, the minimum being six, the maximum 16 days.

Medical Experiences at the Messina Disaster.

Dr. COLMERS of Heidelberg, the chief medical officer of the German expedition to Messina, gave a report of his experiences concerning the injuries produced by the earthquake. He said that the injuries were nearly all very severe, because, the [illegible] night-time, only a very few had an [illegible] from the falling houses. The injured were nearly all found covered with timber, stones, and rubbish within the ruins, and as they had been lying there for several days some of them showed pressure sores and cellulitis leading to gangrene of the limbs. Dr. Colmers stated that dressing with Peruvian balsam gave good results. The compression of nerves by the ruins led in numerous instances to paresis. As to the varieties of fracture observed, fractures of the cranium were relatively rare, but fractures of the vertebral column, the pelvis, and the limbs were very frequent. It was remarkable that after slight injuries of the skull an alopecia sometimes developed.

THE
RECENT FIGHTING IN CONSTANTINOPLE.

(FROM THE BRITISH DELEGATE ON THE CONSTANTINOPLE BOARD OF HEALTH.)

SATURDAY, April 11/24th, 1909, the date of the victory of the Salonica "invaders" over the mutinied garrison of Constantinople, will be as memorable in the history of this city as July 11/24th, 1908, when the now deposed Sultan was reluctantly compelled to grant his subjects a Constitution and Parliamentary government.

Of the events which led up to the recent battle in the streets of the Turkish capital this is not the place to speak at any great length. Briefly the facts were as follows. On the preceding Tuesday week (April 13th) a large number of the troops and marines of the Constantinople garrison mutinied, imprisoned or bound their officers, and flocked to the historial open space close by the mosque of St. Sofia and the Chamber of Deputies. There they were joined by many *hodjas* and *mollahs*, and cried loudly for the Sheriat (the embodiment of the religious law of El Islam), for a change of Ministry, and for the downfall of the Committee of Union and Progress. For a whole day the business of the city was at a standstill; some fighting took place near the War Office between the "loyal" troops and the mutineers; the Minister of Justice and the deputy for Latakia were killed (the latter in mistake for the editor of one of the Committee's organs, the *Tannin*); several other persons were killed or wounded; and the offices of the paper just named, of another organ of the Committee (the *Shourai-Ummet*), and of the Committee itself were sacked by the mob. For the moment the religious reactionaries and mutinied soldiers seemed to have gained the day. Before evening the Ministry had been changed, more or less in accordance with their demands, the leaders of the Committee party were in hiding or in flight, the (late) Sultan had promised complete respect for the Sheriat and an amnesty for the mutineers, and the latter, towards 10 o'clock at night, began to flock back to their barracks in different parts of the town in a state of jubilation. During a great part of that night and the whole of the following day they showed their joy by discharging their rifles into the air, indiscriminately and continuously. The noise thus made was taken at first for that of serious fighting and created, naturally, considerable alarm. Fortunately, however, it was soon learnt that the shots were mere "feux de joie," and the alarm abated. Such firing, however, was by no means free from danger, and within 24 hours a large number of persons had been killed or wounded by stray bullet shots. The exact numbers are not known; one estimate put them at over 500 wounded and about a score killed; but it is thought that these figures are below, rather than above, the truth. The most dangerous place to be in during these wild demonstrations was an upper window, and it was really safer to be in the street and among the demonstrators themselves, who at least made some effort to fire perpendicularly in the air.

After this outbreak there followed a period of ten days of suspense and expectation. During that time the supporters of the Committee rallied. An army was sent from Salonica to invade the capital, restore order, and punish the mutinied troops. The incidents of the Tuesday (April 13th) had undoubtedly been of complex origin. They were the expression, in part, of a widely-felt dissatisfaction at the dictatorial attitude of the Com[illegible] in the Chamber; in part, of [illegible] among the general Moslem [illegible] ard the attempt to introduce reforms on Western lines into this country as contrary to their religion; but in great part they were also caused by the agents of reaction and supporters of the old Hamidian *régime*, and there seems to be little doubt that the gold of Yildiz played an important part in bringing about these demonstrations.

Between April 13th and 23rd the Salonica forces slowly gathered and concentrated at a short distance from the capital. On the afternoon of the 23rd they had reached the suburbs. At dawn on the 24th the invading army entered the town. The Pera division, consisting of (according to a rough reckoning) some 6000 infantry, a certain (not large) number of cavalry, some score or more of field guns, and mitrailleuses mounted on armoured automobiles, marched into the city by the Shishli-Pancaldi-Taxim-Pera road, and thus passed under the windows of my house, situated in the first-named suburb. It was a striking spectacle, this silent invasion of a great capital, in the early hours of a warm spring morning, by men evidently intent on business. It was at 4.45 A.M. that they entered the suburbs; at 5.25 A.M. the engagement began, and from then until 11 A.M. the firing of rifles, cannon, and machine guns continued uninterruptedly. At 7.30 I made my way to the large Military Academy at Pancaldi, some half-mile further in the town and the centre of much of the fighting, and offered my services to help attend the wounded, by that time beginning to be numerous. Some half-dozen colleagues were already there. Several of the cadets' dormitories were turned into hospital wards. The tramcars had been seized by the "invaders" and were converted into ambulance wagons, the stretchers being placed, longitudinally, across the backs of the seats of the open cars; later the same cars served to carry the dead. There was at the Academy a sufficient supply of dressings, antiseptics, and appliances for first aid. By degrees the wounded were transferred to the hospitals. Between 60 and 70 had passed through our hands before noon.

The majority of injuries were Mauser rifle wounds. In most instances the bullet had traversed the body or limb; in fact, in not a single case that came under my immediate care did the bullet remain in the body. I have since seen, however, in the hospitals cases where the bullet remained in the tissues or in one of the great cavities, and has had to be removed by operation or left in, according to circumstances. In the case of penetrating wounds, the wound of entrance was usually distinctly smaller than that of exit; but this was not invariably the case, and in more than one instance the difference in size between the two wounds was trifling; round neither was there, as a rule, much damage to the soft parts, and such wounds have since healed rapidly and well, even when the shot had passed through one of the cavities of the body. In one case the [illegible] the left buttock, had [illegible] muscles, and escaped [illegible] the man had been in a stooping, almost recumbent position at the moment of being struck. Several other patients were wounded in the back in the following circumstances. At the height of the engagement the mutineers raised the white flag and the invaders advanced over the open ground to receive their surrender, but on approaching the barracks a murderous fire was opened on them and they were compelled to retire hurriedly, leaving about a score of dead on the ground. It was rare in any of the cases of rifle wound to see much shattering of the bones or soft parts. In a few, however, compound fractures of the long bones of the arm or leg have since necessitated amputation. In one instance the patient had a compound fracture of the right radius and no less than six other bullet wounds in different parts of the body; he is now doing fairly well and it is hoped that he may recover. Cannon-shot injuries were, of course, much more extensive and serious; but such injuries were rarer among the wounded than among the dead. In bullet wounds hæmorrhage was usually insignificant in amount. Shock was well marked in many cases, and more or less present in all. Many of the men were already in a tired condition before the engagement began. It appears to be established now beyond doubt that the arrival of the army in the city was greatly hastened at the last moment, as otherwise very serious disorders (some say a general massacre) in Stamboul were inevitable. Consequently many men of the invading army had marched all night, from Makrikeui, a distance of some 15 miles or so, and it is stated that many of them had had little in the way of food for several hours before the engagement began. This is to some extent confirmed by the fact that a large number of the men already showed signs of exhaustion as they marched into town in the early dawn; and later, at the height of the engagement at the Military Academy, I saw many of them, when not employed in serving the guns, lie down and appear to fall asleep in the shade of the ammunition wagons, not 30 yards from where the cannon were being fired. In one instance a soldier of the invading army was brought into the Academy, uninjured in any way, but in a state of acute hysteria brought on by the nerve strain, the heat, and the deafening noise of the battle which was being actively carried on under our windows. It must be rare to see a case of this nature in the male subject, except in war-time. From the rapid examination that was alone possible in the circumstances I noted that the pupils were rather but not excessively dilated and equal; the pulse was rapid but fairly good; the patient was unconscious of his surroundings but sensitive to pain, and the reflexes were not abolished; he was crying out much as does a patient in the delirium of high fever. An hour later when I re-inquired as to his condition, I found his bed occupied by another, and [illegible] their [illegible] or patient. The noise of the engagement, the scene of which may be said to have extended from the Military Academy itself (where it had first begun) for some three-quarters of a mile in a southerly direction, along the main tramway route leading to Taxim and Pera proper, was at times literally deafening. There was much rifle-firing in the near neighbourhood of the building; machine guns were being worked some distance away, but one battery of field guns was drawn up under our windows in the parade ground of the Academy, along the southern front of the building. From there they [illegible] rate, did not use them in reply, it was possible to watch, with a fair degree of safety, from our windows the effect of the shot. It was in truth an absorbing spectacle. The shot used appears to have been both shrapnel and heavy shot; the former, at that range, exploded, not in the air, but at the moment of striking the building; the damage done was less than might have been anticipated, and the building, of stout stonework, resisted to the end, the walls still standing, though jagged and torn with holes in a hundred different places. The firing ceased at 11 A.M.; but the Tash-Kishla men still held out. Later in the afternoon, towards 5 P.M. (when I was once more at the Academy), the artillery, which had been temporarily withdrawn, took up again the position they had occupied in the morning, and for a time a fresh bombardment seemed inevitable, but shortly after the mutineers surrendered.

By that time the large majority of the wounded had been transferred to the Hamidieh and other hospitals in the neighbourhood. Between 60 and 70 in all had received first treatment in the Academy. The hospitals that received most of the wounded on the Pera side of the Golden Horn were the Hamidieh, the Gumush-Su, the Armenian Hospital of Sourp-Agop, and the French Hospital in Pera. The wounded in Stamboul were treated in hospitals situated on that side of the Golden Horn. It is extremely difficult to obtain definite figures for the total number of casualties, but the following estimate of a staff officer is perhaps as near the truth as it is possible to get at present; the figures are, at any rate, certainly not above the truth. On the side of the invading army: at Pera, 53 dead and 65 wounded; and at Stamboul, 44 killed and 95 wounded. On the side of the mutineers: at Pera, 240 killed and 475 wounded; and at Stamboul, 57 killed and 110 wounded. This would make a total of 97 killed and 160 wounded on the side of the invaders, and 297 killed and 585 wounded on that of the mutineers, or a grand total of 394 killed and 745 wounded. That these figures are not above, but below (and in the case of the wounded very considerably below) the truth is shown by the fact that 67 wounded, all belonging to the invading army, were admitted to the Hamidieh Hospital alone.

This excellent hospital, situated at Shishli (not a hundred yards from my house), was founded and maintained by the late Sultan, whose now unhonoured name it still bears. A description of it appeared a year or two ago in the pages of The Lancet. It is primarily intended for children. The sudden admission of this large number of wounded men naturally strained its resources, but the call was well met, the army furnishing an abundant supply of surgeons, so that no outside help was needed. The ordinary nursing staff was, however, overtaxed, and the voluntary services of several amateur lady nurses have since been gladly accepted. The hospital itself did not escape injury. At about 6 A.M. a shell, apparently coming from the mutineers at Taxim, struck one of the pavilions, crashed through a window, and shattered the plaster and stone work of an inner wall. Four women attendants were seated in this room, which is not more than some 15 by 10 feet in dimensions, and the shell in its passage blew to pieces the head of one of them without injuring any of the other three. The shattered window and shutters, the battered stone work, and the brain- and blood-bespattered ceiling and walls are still grim to look at. Many other shells exploded in the near neighbourhood, while others buried themselves harmlessly in the earth in the fields and valleys that lie between Shishli and Yildiz.

The city is still, technically speaking, in a "state of siege," but the daily life of the multitude goes on much the same as before, and the outward signs of a military occupation and rule are daily becoming less. A word of unfeigned admiration must be added for the behaviour of the invading army from the time they entered the city. For the past fortnight the city has been entirely in their hands, yet not a single instance has been heard of in which they abused their power, and no citizen has had to complain of robbery, insult, or injury of any kind. In all justice, however, the same or a greater meed of admiration must be given to their late enemy, the "mutineers," who for 11 days had the city no less absolutely at their mercy and behaved equally well to civilians; and this in spite of the fact that they were without officers, were, from a military point of view, entirely out of hand, and (if all reports be true) had their pockets liberally lined with gold from Yildiz.

Constantinople, May 6th.

LIVERPOOL.

(From our own Correspondent.)

A Mace for the University of Liverpool: Dr. Richard Caton's Commemorative Gift.

Shortly before completing his term of office as Lord Mayor of Liverpool, Dr. Richard Caton announced his intention of presenting a mace to the University for use on occasions of public ceremony. The mace has now been received from the makers (Messrs. Elkington and Co.) and was used for the first time at the installation of the new Chancellor on May 8th. It is composed entirely of silver, the head and crown being gilded and enamelled, the stem is oxidised, while the bosses and foot are polished and lacquered. The crown, with orb and cross, and the Royal arms beneath the crown, are symbols of the Royal authority delegated to the University. The head of the mace beneath the crown is divided into four fields or spaces by the following reliefs of Greek divinities: (1) Athene, symbolising the faculties of arts and science; (2) Poseidon, suggesting maritime engineering and the relation of the University to sea-borne commerce; (3) Themis, referring to the faculty of law; and (4) Asklepios, referring to the faculty of medicine. The four fields or spaces thus separated contain enamels of the King's initials and the shields of England, Scotland, Ireland, and Wales; the arms and supporters of the county palatine of Lancaster; the arms and supporters of the city of Liverpool; and the arms of the University of Liverpool. On the head of the mace is a Latin inscription stating that the mace is given to the University of Liverpool by the Lord Mayor as a testimony of the love of the citizens for humane and scientific studies. At the base of the head of the mace is a fillet composed of corn sheaves, suggestive of the Mersey and the sea. The upper part of the mace is connected with the stem by four heads of Hermes, the transmitter of the teachings of the gods, and the patron of the sports of the gymnasium. The spiral band which is seen on the stem of the mace is engraved with the rose of Lancaster, and the bosses with the "planta genesta," the cognisance of King John, the founder of Liverpool. The base contains an inlet coin of King Edward VII., with the date 1908. The mace was presented to the council of the University at its meeting last week.

Installation of the New Chancellor of the University of Liverpool: Distinguished Recipients of Honorary Degrees.

Saturday, May 8th, was an important day in connexion with the University of Liverpool. Two interesting functions took place then in St. George's Hall. The first was the installation of the Earl of Derby as Chancellor of the University in succession to his father, the late Earl of Derby; and the second was the conferment of honorary degrees upon Mr. Arthur Balfour, Lord Roberts, Lord Crewe, Lord Charles Beresford, Mr. Augustine Birrell, Sir Donald MacAlister, Sir John Brunner, Signor Guglielmo Marconi, Dr. Richard Caton, Mr. Robert Gladstone, Professor Paul Vinogradoff, Mr. Francis Darwin, Professor Edward Meyer, Dr. John Lancelot Todd, and the Hon. Charles Algernon Parsons. Academic and official dress were generally worn, and the scene in the hall was strikingly brilliant. The Chancellor and the distinguished honorary graduates were afterwards entertained at luncheon by the Lord Mayor at the town hall, when interesting speeches were delivered by Mr. Balfour, Lord Crewe, Lord Charles Beresford, Mr. Birrell, and others.

May 11th.

WALES.

(From our own Correspondents.)

Workhouse Medical Officers.

The Merthyr board of guardians has decided to appoint a resident medical officer for the union workhouse at a salary of £200 per annum with yearly increases of £20 up to £300. The manner in which the sick inmates of the Merthyr workhouse have been looked after has frequently received commendation at the hands of the Poor-law inspectors of the Local Government Board.—The salary of Dr. R. J. Lloyd Edwards, the medical officer of the Swansea workhouse, has been increased from £500 to £550 per annum. Dr. Edwards is not a resident officer, but holds the positions of district medical officer and public vaccinator.

A Second Hospital for the Rhondda Valleys.

Although the population of the Rhondda Valleys is well over 120,000 persons, there is only one cottage hospital in the whole district. It is situated at Porth at the junction of the two valleys and is therefore a considerable distance from the upper parts of both valleys. The Porth Hospital was founded in 1895 mainly through the efforts of the late Mr. Henry Naunton Davies, M.R.C.S., who was the first to receive the gold medal for distinguished merit, founded in 1877 by the British Medical Association. Quite appropriately the hospital is situated only a few hundred yards above the Tynewydd Colliery, where in April, 1877, a boy and four men were imprisoned without light or food for ten days, and in connexion with whose rescue Mr. Davies and other surgeons displayed conspicuous courage. During many years past attempts have been made, hitherto unsuccessfully, to establish hospitals in other parts of the valleys. There now appears to be some likelihood of a project for the erection of an institution near Pentre meeting with a better fate than others have done. Pentre and Ystrad are two populous districts some five miles from Porth, and a suitable site in either would serve the needs of a very large area A committee, consisting of two workmen and one official from each local colliery, has been formed to choose a site and to consider the best means of carrying out the scheme

Caerphilly Isolation Hospital

The colliery districts in South Wales are at last being well supplied with isolation hospitals Almost the first of any pretensions was built by the Rhondda urban district council in 1899, and very shortly afterwards the neighbouring district of Pontypridd was provided with an excellent institution within a few miles of the town The Aberdare urban district council has decided to erect suitable buildings as soon as plans and other preliminaries are completed, and on April 27th last a well designed hospital was opened at Caerphilly, an urban district with a population of some 25,000 persons situated on the eastern border of Glamorganshire The site, which is about two and a half acres in extent, is on the side of the mountain nearly a mile from the town There are three ward pavilions, with accommodation respectively for ten, eight, and four patients They are designed somewhat on the Local Government Board plan, with a nurses' duty room dividing two wards and sanitary annexes at each end In the two largest pavilions there is a convalescent room on the second storey in the middle of the block The administrative block has 11 bedrooms, so that it would not need enlargement in the event of more pavilions being erected The remaining buildings include a laundry, stables, mortuary, and discharging rooms The cost of the undertaking was approximately £10,000, or about £450 per bed

Deficient Water supplies in Carmarthenshire Schools

In the report which was presented to the Carmarthenshire education committee by Mr L M Bowen Jones upon the 23 schools in which he carried out the medical inspection of the school children in 1908, nothing is more noticeable than the large number of schools which are badly supplied with water In ten of them there is said to be no supply at all while connected with two others there are polluted wells In two schools water is obtained from spouts some yards distant, and in one from a dip well 150 yards away which is liable to pollution by cattle The standard of cleanliness must obviously be a low one in these schools

May 11th

SCOTLAND

(FROM OUR OWN CORRESPONDENTS)

The Glasgow Medical Faculty and the General Medical Council

Dr David N Knox has been elected the representative on the General Medical Council of the Glasgow Faculty of Physicians and Surgeons in succession to the late Dr Lindsay Steven

Partick and District Medical Society, Glasgow

A highly successful session of this newly formed society was brought to a close on April 29th, when the annual business meeting was held, Dr Arthur Mechan, the retiring President, being in the chair Practically all the medical men of the district have now become members of the society, and during the session many subjects of considerable interest to the medical profession have been discussed Among such subjects may be mentioned The Notification of Phthisis, the Relation of Practitioners to District Nursing Associations, and the Conditions and Remuneration in Contract Practice In the case of club practice the members have bound themselves to accept not less than the minimum annual fee approved of by the society, i e, 4s per member The following office bearers were elected for the ensuing session —President, Dr J Gibson Graham, Vice Presidents, Dr W Snodgrass and Dr John Morton, Secretary, Dr A W. M Sutherland, Recording Secretary, Dr J King Patrick, Treasurer, Dr John Gracie, Council, Dr D Westwood, Dr W A Caskie, Dr D J Mackintosh, M V O, Dr J Scott, Dr J Hunter, Dr W S Paterson, Dr John Taylor, and Dr Arthur Mechan

Improved Public Health in Renfrewshire.

The death rate for last year in Renfrewshire was 11 777, and this is stated to be the lowest on record in that district The infantile death rate in the lower ward was 62 per 1000 children born and is phenomenally low, the lowest death rate hitherto recorded being 73 The most notable circumstance during the year probably is that for the first time there has been no prosecution under the Public Health Act, and that, too, although the standard of sanitation in the county, instead of being lowered, has steadily, if insensibly, been raised since the inception of the Public Health Department in 1891

School Nurse for Dunfermline

The medical inspection of school children has already been carried out in all the larger towns, and now the smaller centres are turning their attention to the matter Dunfermline, however, has gone one better, and has appointed a school nurse in connexion with the medical inspection of children at a salary of £80 per year Dunfermline school board is in the fortunate position of having behind it the Carnegie trustees, who have offered to pay the nurse's salary

Death of Dr C M Macrae

By the death of Dr Charles Mackenzie Macrae of Stornoway, Lewis has lost one of its oldest inhabitants, and one who did much for the welfare of the island Dr Macrae, who was the son of the Rev Mr Macrae, for many years parish [minister of Barvas, Lewis, died in his residence at Stornoway last week at the advanced age of 91 Three years ago, on account of old age, he resigned the post of medical officer for the Stornoway parish, which he had filled for a period of about 60 years In 1895 he was presented by the inhabitants, and by Lewis people all over the world, with an illuminated address and a purse containing £200, together with a tea and coffee service for Mrs Macrae, in recognition of his 50 years' professional services in the island

The Municipalisation of the Sidlaw Sanatorium

The opposition to the municipalisation of the Sidlaw Sanatorium seems to have met with results A requisition was sent some fortnight ago by three of the town councillors to the Lord Provost, requesting him to call a special meeting of the council to consider a resolution and four alternative proposals The resolution was as follows 'To take a plebiscite of the electors 'for' or 'against' the whole scheme, and communicate the result to the Local Government Board for its guidance " The alternative proposals were as follows (1) To take a plebiscite, and in the event of such plebiscite being against the scheme to abandon the scheme in the meantime and to ask the sanatorium trustees and directors to concur in cancelling the agreement, (2) to abandon the scheme in the meantime, (3) with the concurrence of the sanatorium trustees and directors to hold the agreement as provisional only pending the next municipal election, (4) to take any other action that might be thought proper, including the rescinding or varying of any former resolution of the council The Lord Provost replied that the resolution and the first, third, and fourth proposals were incompetent, and ultimately issued a summons to the members of the council to attend a special meeting of the corporation to be held in the town hall, Dundee, on May 3rd, for the purpose of considering and disposing of ex Bailie Mechan's motion "That the scheme for the municipalisation of the Sidlaw Sanatorium should be abandoned, and that the council accordingly ask the sanatorium trustees and directors to concur in cancelling the agreement made ' The meeting was duly held on May 3rd, when the resolution to abandon the scheme was adopted by 18 votes to 9 A subsequent motion that the sanatorium should be taken over as an institution containing 40 beds, a [illegible] ling t [illegible] een g [illegible] to the effect that a subcommittee be appointed to consider and report as to a scheme under which the medical officer would be empowered to select a certain number of patients suitable for treatment in the sanatorium The desire is that the system should receive a trial The cost of the patients so sent would be met out of the public health rates At a further meeting of the town council held on May 5th a communication was received from the directors of the sanatorium drawing attention to the trouble and expense to which they had been put in connexion with the negotiations which had been instigated by the council, and suggesting that they might get some compensation The flow of subscriptions had to a large extent been diverted, presumably

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Inoculation for Cholera.

COMPARATIVELY little has been heard of late years of inoculation for cholera, probably because there have been no serious epidemics of the disease in large towns or cantonments. The matter has, however, not been lost sight of in one quarter. The number of labourers required for the Assam tea-gardens annually runs into many thousands, and cholera occasionally breaks out among them on the journey. Last year the railway authorities on the Assam and Bengal line were asked to have a hospital carriage on each train carrying coolies, but this was found to be impracticable. Measures were, however, taken to supply fresh water, to disinfect carriages, and to provide accommodation at certain stations for sick persons. Another and more scientific method of preventing any outbreaks is to inoculate the coolies before starting. Correspondence on this subject is mentioned in the annual report of the Indian Tea Association just published. Professor Haffkine, to whom a reference has been made, stated that the inoculation process had been greatly simplified, one dose of serum only being now required, and that only 24 hours' rest is necessary after treatment. It might all the same be advisable to detain persons four or five days before entering infected districts or embarking on steamers, so that a satisfactory state of immunity might be secured. The association has now decided to ask members whether it would be advisable to approach Government on the subject. It would appear, however, that unless the various recruiting agencies act in common no good results can be obtained. Some years ago one firm of labour contractors at Purulia introduced inoculation and carried it on for several seasons. Their business, however, was prejudiced, and they had to discontinue the practice. Professor Haffkine suggests that no undue pressure should be put upon the coolies, only those being inoculated who understood the benefits to be derived, and that efforts should be made to induce the different labour agencies to agree upon a uniform attitude in the matter. This seems the only way in which to gain a fair measure of success, and the Tea Association should be able to bring about such an agreement.

Blackwater Fever.

A letter has been received by the Indian Tea Association from the Government of Eastern Bengal and Assam, stating that as the Fever Commission which had been making investigations in the Dooars was entirely under the control of the Government of India, the Lieutenant-Governor of Bengal did not consider that he would be justified in recommending an extension of the inquiry to Assam until he was in possession of more detailed information regarding the prevalence of the disease there. Orders had accordingly been issued to the Sanitary Commissioner of the province to report whether there were sufficient grounds to justify such a recommendation to the Government of India, and it was suggested that any facts collected, as well as the opinions of medical officers on tea estates, might be communicated to the Sanitary Commissioner. A copy of this letter has been forwarded to the chairman of the Assam branch for his information. It is expected that he will be taking steps to obtain evidence on the lines suggested by Government.

Calcutta Hospitals.

Recent years have witnessed many improvements and developments in hospitals in Calcutta, notably, of course, the Presidency General Hospital and the extensive additions to the Medical College Hospital in the north of the city. The Government of Bengal has now placed the poor of Calcutta under an additional obligation by a much needed extension to the Campbell Hospital in Lower Circular-road. Here two large surgical blocks, one for male and the other for female patients, have been added, providing accommodation for 88 patients of each sex. Both blocks are two-storied and are similar in design, and their appearance from the outside is not unlike that of the new Presidency General Hospital, of course, in miniature. The estimated cost of the extension is Rs. 1,21,317.

Cattle and Game Disease in the Nilgiris.

A bad type of cattle disease is reported as prevalent. It seems that the disease affects game as well as domestic cattle, and that that grand animal, the bison, is perishing in numbers on the Mysore frontier. Travellers on the road between Jeppacandu and Seegoor have come across dead bison and were able to secure the heads and horns, which they brought in to have mounted. Some of these remains show that the best of the herds have thus perished.

Public Health in Bombay.

Plague continues very low in Bombay and the general good health of the city may be gauged from the statistics for January, which show that there were 260 fewer deaths in the month than was the case last January. During the last week of March there were six more plague cases than the week before, but plague is still lower for the time of year than it has been since 1896. The total mortality was 100 lower than in the corresponding week of last year; it was 700 lower than in the same week of 1905. The most satisfactory conclusion to be drawn from the plague figures up to date is that whatever may be the eventual intensity of this year's seasonal epidemic its onset has again been postponed. This means a shortening of the total period for which the city is in the grip of the disease, and last year plague began to decline in April. The rats caught in the raid in the Fort last week were only plague infected to the extent of 2 per cent., and there is trustworthy information that rats are undoubtedly more scarce than usual in the Fort, a state of affairs which may fairly be ascribed to the persistent campaign of the Health Department. A most unsatisfactory point in connexion with the city's health is the freedom with which small-pox is permitted to be imported. The small-pox epidemic is spreading. During the last week of March there were 63 attacks and 19 deaths, and of these cases 27 were imported in the persons of pilgrim passengers off the ships from Jeddah. These people are landed in Bombay suffering from small-pox, and an indefinite number of "contacts" among the ship's passengers are allowed to spread themselves freely through the city. Surely this is a way of deliberately importing disease and death into our midst which ought to receive immediate attention. Perhaps a means of putting a stop to it might be found with the help of the Hajis committee.

April 20th.

Obituary.

EDWARD GEORGE WHITTLE, M.D. LOND., F.R.C.S. ENG., L.R.C.P. LOND.

Dr. Edward George Whittle, who died at Las Palmas last week, for very many years was one of the leading medical men in Brighton. He retired from the profession a few years ago, but unfortunately did not enjoy very good health, and during the last few years was suffering from a heart affection. Early this year he went to Las Palmas in the hopes of deriving benefit from a warmer climate. He wrote home cheerfully, speaking of the progress he was making, and the news of his death came as a great blow to a very large circle of friends. Dr. Whittle received his professional education at University College Hospital, London. He became a Member of the Royal College of Surgeons in 1873, a Licentiate of the Royal College of Physicians and Bachelor of Medicine of the University of London in the next year. In 1876 he became a Fellow of the College of Surgeons and took his Doctorate in 1882. After settling in Brighton he was appointed surgeon to the Royal Alexandra Hospital for Children, and honorary physician to the Brighton and Hove Dispensary for Women and Children. He was the author of a work on "Congestive Neurasthenia; or Insomnia and Nerve Depression," and of several papers in this journal. At the Brighton Health Congress in 1881 he contributed a paper on the Artificial Dieting of Children, and at the annual meeting of the British Medical Association in 1886 read a paper on Melancholia and Insomnia in the Sane. His skill was widely known and he had a large practice both in Brighton and Hove. In 1891 he was elected President of the Brighton Medico-Chirurgical Society. Dr. Whittle was a man of remarkable energy. He indulged in many pastimes and was, perhaps, best known in the athletic world as a tennis player. Twice he gained the distinction of winning the veterans' singles in the All England championship at Eastbourne; also, with Mr. C. M. Perkins, the Veterans' [illegible] many years bathing in the sea all the year round), a skilful musician, and a prominent member of the Masonic craft. He was twice married.

GEORGE ROE CARTER, M.R.C.P. IREL., L.R.C.S. IREL.

Mr. G. Roe Carter, who died on May 3rd in his sixty-seventh year, was a well-known practitioner at Anerley, where for 30 years he enjoyed the confidence of a wide circle of friends and patients. He was also medical officer of health to the Penge urban district council, and in that capacity did not a little towards improving the sanitary condition of the district over which he had charge. Mr. Carter was educated at Ledwich School, Dublin, and at the Meath Hospital. The early years of his professional life were spent at St. Lucia, where he was colonial surgeon and medical officer of health to the island. He was a Fellow of the Royal Institute of Public Health, a member of the Council of the Obstetrical and Gynæcological Section of the Royal Society of Medicine, and formerly a member of the Councils of the British Gynæcological Society and of the Irish Medical Schools and Graduates' Association.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Viscount Candido de Figueiredo Saboia, formerly professor of clinical surgery in Rio de Janeiro and foreign corresponding member of the Paris Academy of Medicine.—Dr. Louis B. Durocher, formerly professor of mental diseases and forensic medicine in Montreal.—Dr. Derville, assistant professor of clinical medicine in the University of Lille.

THE ROYAL SOCIETY CONVERSAZIONE.

SCIENCE was represented in very many directions at the conversazione of the Royal Society which was held at Burlington House on Wednesday last, May 12th. The electrician, the astronomer, the biologist, the physicist, the chemist, the medical man, each alike was certain to find an exhibit having some connexion more or less with his own particular branch of study. Opportunity seems to have been given also on this occasion to those interested in certain developments of applied science to exhibit its triumphs, and it should be added that the exhibits under this head were of general interest.

In the secretaries' room, for example, on the ground floor a most fascinating process for reducing metals to the state of ribbon was in operation. Nothing could be simpler than the method adopted, and since its application is likely to lead to the prevention of industrial poisoning, some prominence may be given to this innovation. Molten metal, it may be lead, tin, zinc, gold, aluminium, is caused to flow through one or more nozzles in a thin stream on to the periphery of a rapidly rotating water-cooled drum. The metal solidifies immediately and it is possible to obtain a ribbon of 1-1000th inch in thickness, and from half a mile to a mile can be obtained from each nozzle per minute. In the principal library Mr. S. Cowper Coles showed some beautiful specimens of glass parabolic mirrors coated with gold. The light reflected by these mirrors has a remarkable penetrating effect in foggy weather, and yet is softer in tone than the light from the silver mirror. Close by were some samples of pitchblende taken from the Cornish mine at Trenwith. Mr. Francis Fox explained that the best specimens contained 33 per cent. of uranium oxide, and from 150 to 200 milligrammes of radium per ton of ore. There were also some fine specimens of uranium salts shown.

One of the most remarkable exhibits was that shown by Professor Norman Collie. This consisted of various forms of glass tubes containing neon and mercury, which when shaken together, even at ordinary pressures, were seen to glow with a strange orange-red light. The phenomenon has, so far, received no explanation. Another interesting glow effect was shown by the Rev. H. V. Gill in his vacuum tubes containing a strip of palladium foil or palladinised platinum foil. On passing the current through [illegible] and around the incandes- [illegible] -blue glow. Sir William Ramsay's exhibit of liquid radium emanation, a subject recently referred to in our columns, attracted considerable interest. It can be reduced to a solid which, when cooled further, phosphoresces very strongly and more intensely than does the gas.

As we have said, medical studies were well represented. Dr. A. D. Waller, for example, gave a demonstration of the electrical variation of the human heart and of the dog's [illegible] galvanometer. The subject was [illegible] who regarded the proceedings [illegible] amused resignation. He was connected with the galvanometer by standing with his near fore and off hind foot in two pans containing salt water and the electrodes. The apparatus was also fitted with vessels into which visitors could dip their hands and so see the diphasic variations in their own heart beats, but probably owing to the fact that the electrical resistance of the skin is very high, unless the [illegible] e, the human [illegible] We intend [illegible] an account of Professor Einthoven's recent work in this field.

[illegible] exhibited a fine series of diagrams illus- [illegible] first time in this exhibit, sarcoma being developed upon an antecedent carcinoma. Lieutenant-Colonel W. B. Leishman, R.A.M.C., presented microscopic specimens illustrating the transmission of tick fever. The various stages of the tick's life were also illustrated by living examples, and the microscopic specimens showed the alterations which the spirochætæ appear to undergo in their passage from one generation of tick to another. Mr. S. G. Shattock exhibited the microscopic section already referred to in our columns of the aorta of King Menephtah (traditionally regarded as the Pharaoh of the Exodus), showing senile calcification. Mr. L. Doncaster exhibited a beautiful collection of currant moths illustrating sex-inheritance, and Professor Karl Pearson, with Mr. E. Nettleship and Mr. C. H. Usher, presented to view a very interesting series of plates illustrating a forthcoming monograph on albinism. The Director of the Royal Gardens, Kew, showed his experiments with cyclamen seedlings, which normally have only one cotyledon; if this be entirely removed the second cotyledon will develop. If only the lamina be cut off a new lamina will bud out from the side of the leaf stalk near the apex, and on the removal of this second lamina a third can be induced to grow out from its stalk just below the apex. If the lamina be mutilated and not wholly removed, new growths will also be formed.

Sir Archibald Geikie, K.C.B., D.C.L., received the Fellows and guests, and there was a large and distinguished company present.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the First Professional Examination for the Licence in Dental Surgery held last week the following gentlemen were approved in the subjects indicated below:—

Mechanical Dentistry and Dent [illegible] Adams, Guy's Hospital, Sidni [illegible] Hospital, Edwin Randolph B [illegible] Samuel Beare, National Dental [illegible] Hospital; Walter Sydney Bevis [illegible] Fisher Camp, Guy's Hospital; [illegible] Royal Dental Hospital, Regina [illegible] pital; William Dod Dye, Roya [illegible] Geekie, National Dental Hos [illegible] Royal Dental Hospital, Alber [illegible] University; Guy William Ln [illegible] Eric Greaves Ireland, Royal [illegible] Oldham Jensen, Royal Dental [illegible] Hospital; Donald Henry McI [illegible] Harold Leonard Meyer, Guy's I [illegible] Royal Dental Hospital, George [illegible] Hospital; Arthur Hugh Spencer Palmer, University College, Bristol; Fred Quayle, Royal Dental Hospital, John Hargrave [illegible] Hospital; Charleston Edmund Rice, Guy's Hospital; [illegible] spital; Sidney Sexton, University [illegible] fred Slade, University College, [illegible] Guy's Hospital; William Suffield, [illegible] ton Tait; Guy's Hospital, Arthur

Cyril Tuft, Royal Dental Hospital; Basil William Tyson, University College, Bristol; and George Trevor Yonge, Royal Dental Hospital.

Mechanical Dentistry.—Harold Edgar Bower, Royal Dental Hospital; Oscar Bullock, Royal Dental Hospital; Henry O'Neil Butler, Royal Dental Hospital; Henry Charles Corke, Guy's Hospital; Henry Oswald Dumayne, Guy's Hospital; John Eric Rhys Evans, Guy's Hospital; Frederick Amos Jaques, Guy's Hospital; Roy William List, Royal Dental Hospital; George Bertrand Lucas, Royal Dental Hospital; John Dudley Melhuish, University College, Bristol; Owen Colville Morphy, Royal Dental Hospital; Wilfrid Stephen Ollis, Guy's Hospital; Cyril Arthur Pollard, Guy's Hospital; Gordon Evelyn Rowstron, Guy's Hospital; Frank Percival Sturdee, Royal Dental Hospital; William Vere Taylor Styles, National Dental Hospital; and John Herbert Wiles, Guy's Hospital.

Dental [illegible] ert, Royal Dental Hospital; Henry James [illegible]. Gordon Comyn, Royal Dental Hospital; [illegible] Guy's Hospital; Joseph Coplans, Royal [illegible] eroy Gillett, Michigan University; Arthur Oliver Gray, Royal Dental Hospital; Robert Daniel Gregg, Liverpool University; Robert John Harley-Mason, Royal Dental Hospital; Harold Harrison, Guy's Hospital; Harold Holburn, Durham University; Samuel Carson Huggins, Dublin and Royal Dental Hospital; Frederic Winbolt Lewis, Royal Dental Hospital; Claude Vernon Osb[illegible] C[illegible]ge, Bristol; Ronald Victor Payton, Birmingh[illegible] Ernest Frederick Peaty, Guy's Hospital; [illegible] P[illegible]n, Royal Dental Hospital; Richard Angwin Rail, Royal Dental Hospital, Warren Longtoft Roberts, Lee[illegible] Stacey Robinson, Birmingham University; [illegible], Royal Dental Hospital; Alfred Edmund Vi[illegible] Hospital; Claude Taylor, Royal Dental Hosp[illegible] Marling West, Royal Dental Hospital; Sidney White, Royal Dental Hospital; Charles Eustace Williams, Royal Dental Hospital; William Hector Wotton, Guy's Hospital; and Edgar Olyve Yerbury, Guy's Hospital.

FOREIGN UNIVERSITY INTELLIGENCE.—*Greifswald:* Professor Stern of Breslau, Director of the Medical Polyclinic there, has accepted the invitation to the chair of Medicine, together with the charge of the Medical Clinic.—*Lemberg:* Dr. Georg Modrakowski has been recognised as *privat-docent* of Pharmacology.—*Munich:* Dr. Heine of Königsberg has been appointed Extraordinary Professor of Otology in succession to the late Professor Bezold.

KING'S COLLEGE (UNIVERSITY OF LONDON).—The following two advanced courses of special lectures on Physiology will be delivered in the Physiological Laboratory, King's College, London, during the present term: 1. A course of eight lectures on the Senses of Hearing, Taste, and Smell, by Professor C. S. Myers, on Fridays (May 13th to June 25th), at 4.30 P.M. (This course was commenced on May 7th.) 2. A course of four lectures with experimental demonstrations on the Secretion of Urine, by Professor T. G. Brodie, on Mondays (June 7th to 28th), at 4.30 P.M. These courses are free to all internal students of the University of London and to all medical practitioners on presentation of their visiting cards.

DONATIONS AND BEQUESTS.—Lord Sandhurst, treasurer of St. Bartholomew's Hospital, has received from the Company of Merchant Taylors £500, being the first moiety of a further grant of £1000 towards the building fund of the hospital.—By the will of the late Mrs. M. M. F. MacEwan the London Hospital will receive £5000 and the Hospital for Incurables, Putney, £2000.—Under the will of the late Mrs. L. J. Grice the West Bromwich District Hospital will benefit by a sum of £1000.—The late Mr. John Smith of Adderley, Monifieth, Forfarshire, has by will left £2000 to the Dundee Royal Infirmary, £1000 to the Dundee Royal Victoria Hospital for Incurables, and £500 to the Gerard Cottage Hospital, Monifieth.

LONDON HOSPITAL MEDICAL COLLEGE (UNIVERSITY OF LONDON).—A course of four lectures on Statistical Methods in Physiology and Medicine will be delivered in the physiological theatre of the College at 4.30 P.M. on Fridays, May 21st, June 4th, 11th, and 18th, by Mr. M. Greenwood, jun. (director of the London Hospital Statistical Department and senior demonstrator of physiology in the Medical College). The lectures will deal with: I. General objects of the theory of probability, its relation to observational and experimental science; some practical applications of elementary principles to examples of medical interest. II. Variation and its quantitative study, illustrations of method: (1) phagocytic counts and (2) age incidence of diseases. The conception of a "probable error," with examples. III. Correlation and its quantitative study, illustrations: (1) weights of viscera; (2) caisson disease and body weight; (3) incidence of plague in rats and men; and (4) incidence of phthisis in husband and wife. IV. Statistical fallacies, material fallacies, and analytical fallacies, with illustrations. This course, which has been approved by the Senate under the scheme for advanced lectures in physiology, is free to all students of the University and others on presentation of their visiting cards. It is proposed to hold a practical class in connexion with this course, for particulars respecting which applications should be addressed to the Warden of London Hospital Medical College.

THE CHEMISTS' EXHIBITION.—The organisation of this annual exhibition is evidently a success, since the present year witnesses the fifteenth of the series. The proceedings were opened on May 10th and the Horticultural Hall in Vincent-square, Westminster, was again chosen for the occasion. It must be admitted that drugs and the multiple accessories of the trade provide an abundance of material wherewith to make the whole scene a picturesque one. The stalls were admirably arranged and the ingenuity with which the various goods were displayed was the subject of very general remark by the visitors, among whom were, besides those more or less interested in the commercial aspects of the exhibition, a good number of medical men and hospital nurses. Proprietary articles were fairly strongly represented and there were many examples to be seen of real pharmaceutical advances. The exhibition is in many ways instructive, and new ideas of value to medical men are almost certain to be gleaned from a visit to it.

BAD-NAUHEIM AT EVERSLEY, HANTS.—On Saturday, May 1st, a number of leading physicians from London and elsewhere availed themselves of the invitation of Dr. J. G. Garson to visit the Eversley Sanatoria and to inspect the new Nauheim baths he has recently erected there, which were opened to the public for the first time that day. The weather was fine and several of the company present motored down from town. The sanatoria are situated in one of the most beautiful and healthy districts of North Hampshire, familiar to many as that in which the late Charles Kingsley lived for many years while rector of the parish and where he wrote several of his best known works. The sanatoria comprise two distinct establishments, Moorcote and Glencote. In the former tuberculous cases are treated on the Nordrach system, while in the latter are received patients suffering from non-tuberculous ailments, such as affections of the heart and blood, disorders of the nervous system and metabolism, general debility, and convalescents after illness. It is in connexion with this latter establishment that the new bath-house for Nauheim and other baths has been inaugurated. The Moorcote Sanatorium for the Open-air Treatment of Tuberculosis has been established for ten years, but has during the last three years undergone many improvements at the hands of the present proprietor. The Glencote Sanatorium was opened for non-tuberculous patients about three years ago on the model of the Luisenheim at St. Blasien in the Black Forest. The arrangements for the housing and treatment as well as for the comfort and amusement of patients were shown. The sun and air bath situated in a clearance in the neighbouring woods and the tracts on the lawn for the practice of Frenkel exercises by patients suffering from locomotor ataxy are notable features of the armamenta available for the treatment of affections of the nervous system. After repeated visits to many German and other spas, Dr. Garson came to the conclusion that the most generally useful and efficient for the treatment of the greatest number of complaints are the Nauheim baths which have also been reproduced more or less perfectly in many health resorts in Germany, but usually very imperfectly in England. The special features of the Bad-Nauheim bath waters are that they contain alkaline salts, chiefly chlorides and [illegible] arged with carbonic acid gas, and they [illegible] at temperatures varying from 30° to 34° C. according to the spring. The water is impregnated with the gas, but before the patient enters the bath no bubbling of the gas through the water is apparent, although on getting into it his body becomes at once covered over with a layer of exceedingly minute beads of carbonic acid gas which differences in temperature cause to be liberated from the water. To produce these saline carbonic acid baths artificially bicarbonate of soda and hydrochloric acid, besides the other essential salts of Nauheim bath water, have been employed, or CO_2 has been made to pass through finely perforated tubes placed on the floor of the bath tubs. To get a good artificial CO_2 bath, however, the water used for the bath has to be charged under considerable pressure by means of suitable apparatus. Dr. Garson has procured from Berlin the newest and most improved apparatus for charging the water of the Nauheim baths at Eversley with CO_2 gas by which the highest degree of impregnation is obtained, and with it is able to produce the strongest CO_2 Nauheim baths or the weakest as required. The process by which this is effected was explained to the visitors. The chemicals used in the preparation of the baths are imported direct from Bad-Nauheim. The baths are taken on alternate days and are supplemented by drinking Nauheim waters, a stock of which has been procured. In heart cases Nauheim remedial gymnastics and massage are given on the days when the patient has no bath. The whole Bad-Nauheim treatment has therefore been arranged for and is now available for patients who prefer to have the treatment at home. Besides the Nauheim baths, pine and other medicated baths, Scotch douche, needle and rain baths have been installed. All the baths are available for patients at very moderate charges and at cost price to members of the medical profession requiring treatment.

THE RECENT POOR-LAW REPORT: A CONFERENCE. With a view to attract public attention to the important matters raised in the report of the Royal Commission on the Poor-laws and Relief of Distress, the British Institute of Social Service has arranged for a two days' non-partisan conference [illegible] Lord Mayor. The intention is that after the paper has been read the chairman shall make a reply and that the meeting shall then be thrown open for discussion with a time-limit for speeches. No resolutions will be put to the meeting. *The following programme has been arranged.* Session No. 1.—May 18th, 11.30 A.M.: The Machinery Proposed, opened by Mr. Sidney Webb, L.C.C.; chairman, Mr. T. Hancock Nunn. Session No. 2.—May 18th, 3 P.M.: The Treatment of Infants and Children, opened by Mr. George Lansbury; chairman, the Earl of Stamford. Session No. 3.—May 19th, 11.30 A.M.: The Treatment of the Able-bodied, including the Unemployed, opened by the Rev. Russell Wakefield; chairman, Mr. Walter Hazell. Session No. 4.—May 19th, 3 P.M.: The Treatment of the Aged and Sick, opened by Mr. J. R. Brooke; chairman, Mr. Percy Alden, M.P.

THE ROYAL SANITARY INSTITUTE.—The annual dinner of the Royal Sanitary Institute took place on May 11th at the Langham Hotel under the chairmanship of the Duke of Northumberland, President of the Institute. About 80 members and their guests were present, including Sir Dyce Duckworth, who proposed the toast of "The Navy, the Army, and the Territorial Forces," reply being made by Sir Alfred Keogh. The latter, in response to interest audibly manifested by those present in his work in connexion with the Territorial Army, spoke in high terms of the zeal which he had found and which he had been able to stimulate and render effective in the direction of sanitary organisation in that branch of the service. He expressed the hope that such work would ultimately reduce the work of the hospitals in war more and more to the care of the wounded and relieve them of the necessity of providing for victims of disease. To the toast of "The Houses of Parliament," proposed by Sir Alexander Binnie, Sir Francis Sharp Powell, M.P., who, by the way, first sat in the House of Commons in 1857, replied, commending the "wholesome discontent and desire to move forward" which was responsible for useful reform. Next "The Royal Sanitary Institute" was proposed by the chairman, who alluded to the necessity which must arise out of a growing dissatisfaction at the advance of rates, for local authorities to press for State assistance to enable them to bear the burdens laid upon them by legislation. These burdens took the form of a *trinodis necessitas*, composed of roads, care of children, and sanitation. Mr. H. D. Searles-Wood, chairman of the Council, replied on behalf of the Institute. In replying to the toast of "The Guests," proposed by Mr. A. Wynter Blyth, Colonel T. W. Harding, President of the annual congress to be held at Leeds this year, promised the members of the institute a hospitable welcome at Leeds when they assemble for their congress in that city. Among were Sir Shirley Murphy, the Right Hon. Dr. Robert Farquharson, Sir John Tweedy, and Sir Henry Burdett. Colonel J. Lane Notter, deputy chairman of the Council; Dr. P. Boobbyer, chairman of the Exhibition Committee; Mr. Henry Adams, chairman of the Board of Examiners; and Mr. E. White Wallis, secretary to the Institute, also supported the President.

THE NEW PATHOLOGICAL BUILDING AT ST. BARTHOLOMEW'S HOSPITAL.—The new pathological extension of St. Bartholomew's Hospital, the foundation-stone of which was laid by Lady Ludlow at the end of 1907, was opened on May 7th by the Lord Mayor. The building, which was designed by Mr. E. B. I'Anson, architect to the hospital, is situated between the King Henry VIII. gateway and the hospital library and museum, and consists of six storeys containing laboratories for clinical and chemical pathology, morbid histology and bacteriology, and a pathological library and a post-mortem room. The Lord Mayor, who was received by Lord Sandhurst (treasurer), Dr. Norman Moore, Mr. Harrison Cripps, Dr. F. W. Andrewes, Dr. J. H. Drysdale, and Miss Stewart, was presented by the treasurer on behalf of the governors of the hospital with an address. In his reply, the Lord Mayor said that the opening of the pathological block meant the increased usefulness of the hospital, by which not only the citizens of London would benefit but the great world outside as well. The great advances that had been made in curative and preventive medicine during the past 20 years were due largely to the advances made in the study of pathology. The Lord Mayor concluded with an appeal to the City of London to support St. Bartholomew's Hospital.

INSTRUCTION IN METROPOLITAN FEVER HOSPITALS.—At a recent meeting of the Metropolitan Asylums Board the hospitals committee reported having considered a letter from Dr. H. R. Kenwood, professor of hygiene at University College, London, in which he asked, on behalf of members of his class in public health, whether "the existing conditions under which they are at present signed up for the three months' attendance upon a fever hospital which is required by the regulations for the diploma" can be modified. In pursuance of instructions the medical officer for general purposes (Dr. H. E. Cuff) submitted a full report on the whole subject, giving in detail the steps which led to the adoption of the present regulations, and pointing out that the present scheme does not accommodate itself to the circumstances of the large majority of the candidates for the diploma in public health. The existing arrangements require candidates who wish to study administration in the hospitals of the Board to reside therein. The committee had gone into the matter very carefully, and while it was of opinion that the present arrangements involving residence should be retained unaltered, they thought that steps should be taken, as suggested by Dr. Cuff in his report, to supplement the facilities now afforded by instituting at two of the Board's hospitals classes at which candidates for the diploma may receive instruction in administration without being compelled to enter into residence. They recommended :—

[illegible] officer for the general purposes.

This was agreed to without comment.

PROSECUTION OF A [illegible] UNDER THE MIDWIVES ACT: [illegible] Eccles (Lancs) police court o[illegible] heard under Section XI. of the Midwives Act, in whic[illegible] Mr. George Sidley, L.R.C.P. Edin., was proceeded aga[illegible] by the Director of Public Prosecutions, who was [illegible]sented by Mr. Lewis, for aiding and abetting Sara[illegible] Marsh fraudulently to procure admission to the [illegible] Roll, Marsh being charged with the major offence. Sidley was defended by Mr. F. W. Ogden, instructed [illegible] Mr. Hempson, solicitor to the Medical Defence Un[illegible] According to counsel's opening speech and the eviden[illegible] Mr. Sidley, who is a prominent m[illegible] filled in a certificate stating that Sarah Ann Marsh had been in *bona-fide* practice as a midwife since 1899, and that she was trustworthy, sober, and of good moral character. This certificate was forwarded in due course to the Central Midwives Board and upon the strength of it Marsh was registered on the Board's roll in April, 1905, under Section II. of the Midwives Act. In February of this year she was convicted at the Eccles police court of being drunk and incapable. This fact was reported to the Central Midwives Board with the result that further inquiries were made and it was found that Marsh had been repeatedly convicted of similar offences in the same court, eight of these convictions having occurred before Mr. Sidley had given his certificate and four subsequently. On March 23rd her name was struck off the Roll of Midwives in consequence of these disclosures. The matter was brought before the Director of Public Prosecutions who considered that proceedings should be taken against Mr. Sidley for culpably reckless conduct in signing the certificate. The chief evidence for the prosecution was given by Mr. George William Duncan, secretary to the Central Midwives Board, and Inspector Howarth, who proved the convictions against Marsh. For the defence Mr. Ogden submitted that there was no evidence to prove that Mr. Sidley was aware of Marsh's convictions or drunkenness when he gave the certificate, and that his action in doing so had in no way been proved false or fraudulent. He had not even issued the certificate recklessly. Several near neighbours of Mrs. Marsh were unaware of her drinking habits, which could not therefore be rightly called notorious. Mr. Sidley had only certified that he had known Marsh for years and knew nothing wrong against her, which was quite true. Counsel asked the magistrates to dismiss the summons, and after a short deliberation the chairman announced that they were unanimous in doing so, but that Mrs. Marsh would be committed for trial at the next quarter sessions. We congratulate Mr. Sidley and the Medical Defence Union on the issue of the case.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Parliamentary Session.

PERHAPS it is rather soon to write definitely as to the probable length of the Parliamentary session. Members, however, are becoming convinced that it will extend further into the autumn months than is usually the case. In fact, one report is current that if the Government is to carry its Budget proposals substantially intact it will be September before Parliament is prorogued.

The Budget.

Some days and even weeks often pass before the ramifications of an elaborate Budget are laid bare. The financial proposals of Mr. LLOYD GEORGE are more than usually complicated, and with respect to some of them modifications may be made after debate has revealed the incidence of the new imposts. For instance, the Chancellor of the Exchequer is giving careful consideration to the advisability of granting

S[illegible]cial rebate on spirits used in the manufacture of medicine. With

£20[illegible] to the question of a rebate on the duty on the petrol used by

Royal [illegible]en in their motor-cars, the Government exhibits less disposi-

l f[illegible] illustrations. This course, which

COLLINS has produced a Bill giving effect to his views. He states that it virtually reproduces the powers sought by the London County Council three years ago. The single operative clause is designed to allow that body to constitute the administrative machinery and acquire the lands and buildings necessary for the establishment and maintenance of an ambulance service. In presenting the Bill Sir WILLIAM COLLINS has the support of Colonel LOCKWOOD, Sir WALTER FOSTER, Sir WILLIAM BULL, Mr. DICKINSON, Mr. CORRIE GRANT, Mr. STEADMAN, Mr. STRAUS, Mr. J. W. WILSON, and Mr. WATERLOW.

East India (Contagious Diseases) Return.

Nearly 11 months have elapsed between the date on which the return with regard to contagious diseases in India was ordered by the House of Commons and its publication this week. It shows in respect of each cantonment or other place where soldiers are stationed in India the methods in force for dealing with women suffering from venereal disease.

The Medical Acts (Amendment) Bill.

Mr. COOPER's Medical Acts (Amendment) Bill, which deals with the administration of anæsthetics, has up to the present failed to secure a second reading. The motions for its rejection still remain on the notice paper. Mr. COOPER has indicated his willingness to have the Bill referred to a Select Committee by giving notice of a motion to do so after it has received a second reading. One of the advantages of sending a Bill to a Select Committee is that evidence both for and against its proposals may be heard. On the other hand, when a Bill does go to a Select Committee the delay occasioned by the hearing of witnesses and the preparation of a report is generally fatal to its progress during that session. If a good case is made out for it before the Committee it is placed in a stronger Parliamentary position in the following year.

Milk Legislation.

Mr. BURNS, the President of the Local Government Board, has not yet had an opportunity of introducing the promised Bill on milk-supply. At present the Budget monopolises the time and energies of the House of Commons, and this fact would be an obstacle to the progress of the measure if it were introduced. Although the right honourable gentleman has the Bill drafted and is desirous of submitting it to Parliament, those who are anxious to see it formally placed before the House are beginning to despair of its introduction before Whitsuntide. The longer the measure is delayed the less probable does its passage into law this year become. No one doubts the desire of Mr. BURNS to carry legislation on the important subject of milk-supply, but sometimes the best intentions of a Minister are checked by the obstacle of a crowded Parliamentary session.

HOUSE OF COMMONS.

WEDNESDAY, MAY 5TH.

The Recommendations of the Belfast Health Commission.

Mr. DEVLIN asked the Chief Secretary to the Lord Lieutenant of Ireland whether he could state what steps, if any, had been taken to carry out the recommendations of the Belfast Health Commission.—[illegible] the following written reply: The recommenda-[illegible] [illegible]lth Commission were so various and complex [illegible] [illegible]ction which would accurately cover a[illegible] matters pending the is[illegible] put other matters in trai[illegible] moreover, after conside[illegible] of the Commission, addr[illegible] regard to such of the [illegible] received suitable attention.

Poor-law Medical Relief to Married Women.

Mr. BENNETT asked the President of the Local Government Board whether his attention had been called to Dr. J. C. McVail's statements in his Report to the Poor-law Commissioners that in some unions married women who were ill and needed relief in the workhouse infirmary were unable to obtain it unless the husband himself came into the workhouse, because the guardians believed that they could not legally admit a wife without a husband; whether he had noticed the case where the guardians believed that they could not take into the workhouse a mother and three children who were suffering from itch unless the father (who was free from that complaint) came in also; and whether he would send a circular to the Poor-law inspectors and guardians informing them that married women [illegible] nursing, and children who were destitu[illegible] [illegible]lly [illegible] [illegible]er [illegible] [illegible]aw

[illegible]RNS wrote in reply: In [illegible] [illegible] Prohibitory Order is in force unions [illegible] must be relieved in the work-an abl[illegible] house, [illegible]nily of such person as may be resident with him or her and may not be in employment. This rule, [illegible] [illegible]exceptions in certain cases, one of which is [illegible] [illegible]elief on account of any sickness, accident, [illegible] affecting such person or any of his or her [illegible] well aware of the law on this point and I have no reason to suppose that guardians and their officers generally are not acquainted with it. I will, however, instruct the inspectors in their communications with the guardians and their officers to bear the matter in mind and to remove any misapprehension which they may find to exist with regard to it.

THURSDAY, MAY 6TH.

The Duty on Spirits and the Price of Medicines.

Mr. LONSDALE asked the Chancellor of the Exchequer whether his [illegible]ntion had been called to the fact that one effect of the proposed increase of 3*s.* 9*d.* per gallon in the duty on proof spirit would be an advance in the price of many medicines; and whether he would consider the advisability of granting a special rebate on spirits used in the manufacture of medicine.—Mr. LLOYD GEORGE replied: I have received on this point a certain number of letters to which I am giving careful consideration.

The Death of a Child by Burning.

[illegible] the framers of the Children Act; and whether he would consider the propriety of amending the law in order to secure that all fires were properly guarded.—Mr. GLADSTONE furnished the following written [illegible] it in the case referred to in the [illegible] to reach a bag hanging on the [illegible] ult that her clothes caught fire. [illegible] rliament against every source of [illegible] Act was intended to meet the [illegible] I am afraid that it would be [illegible] h exceptional circumstances as [illegible]

The New Public Abattoir at Belfast.

In answer to Mr. DEVLIN, Mr BIRRELL (Chief Secretary to the Lord Lieutenant for Ireland) replied The Belfast corporation last autumn decided to proceed with the erection of a new abattoir and the necessary plans had been completed. The corporation deferred taking further action pending consideration of a report to be made by a deputation to visit abattoirs in other countries The Local Government Board understand that the report will shortly be laid before the corporation.

Liverpool Milk supply.

Mr. TYSON WILSON [illegible] Board whether his atte [illegible] it had [illegible] under- [illegible] r to its [illegible] olated. [illegible] ere, as [illegible] council [illegible] them. [illegible] all for [illegible] to have [illegible]

Births, Marriages, and Deaths.

BIRTHS.

GREENWOOD.—On May 9th, at "Reigate," Lower Park-road, Loughton, the wife of M. Greenwood, jun., M.R.C.S., L.R.C.P., of a son.

HARRIS.—On May 9th, at Wimpole-street, the wife of Dr. Wilfred Harris, F.R.C.P., of a son.

HAYMAN.—On May 8th, at "Harewood," Narborough-road, Leicester, the wife of S. Clifford Hayman, F.R.C.S., of a son.

STEAD.—On April 26th, at Ulcombeden, Hawkhurst, the wife of Chas. Clement Stead, M.B., of a son.

MARRIAGES.

BAKER—PARROTT.—On April 29th, at St. Mary's, Hayes, F. C. J. Baker, M.R.C.S., L.R.C.P., to Stella Caroline, younger daughter of E. J. Parrott, M.R.C.S., L.R.C.P., of The Thorn, Hayes, Middlesex.

DEATHS.

BODDY.—On May 6th, at Bloomfield-terrace, Sloane-square, Clarinda Boddy, M.D.

CHAFFERS.—On May 4th, at Abbotsrood, Grange-over-Sands, Edward Chaffers, F.R.C.S. Eng., J.P., aged 67 years.

THOMSON.—On May 7th, at Brisbane, Queensland, John Thomson, M.B., C.M. Edin., aged 61 years.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

PUBLIC INSTRUCTION CONCERNING CLEAN MILK.

THE county council of the West Riding of Yorkshire, in the early part of the year 1907 in conjunction with the county council of the East [illegible] ghs of Bradford, Hull, Leeds, [illegible] mmittee to inquire into the [illegible] of the milk supply of the county. The report of the joint committee has been published, [illegible] practical investigation by Dr. [illegible] tary committee has expressed [illegible] the interests of the public *health to disseminate, as widely as possible, the information* which it contains. The committee has accordingly prepared three leaflets, which we have received and which are based upon the report, for distribution amongst (*a*) housewives; (*b*) farmers and dairymen; and (*c*) retail milk-sellers, and is requesting the borough councils to undertake to distribute the leaflets (*b*) and (*c*) to persons registered by corporations under the Dairies, Cowsheds, and Milkshops Orders and liable to inspection These leaflets are to be supplied free of charge for this purpose and the leaflet (*a*) is to be placed on sale for the benefit of any local sanitary authority desiring to distribute it, at a very moderate price, from Messrs. Sanderson and Clayton of Wakefield. It is much to be hoped that the authorities in question will give their full support to the scheme. The practical application of information conveyed by scientific reports is an encouraging sign of progress. Only too often in the past have such reports been received and forgotten. The leaflets which have been sent to us are written in plain and simple language and printed in clear type They may well prove useful sanitary tracts throughout an area wider than the Ridings.

MEDICAL WOMEN REWARDED FOR GALLANTRY.

His Highness the Nizam of Hyderabad has graciously commanded that Miss Pinto and Miss Corea, house surgeons at the Victoria Zenana Hospital, be promoted to the grade of senior assistant surgeon in recognition of their gallant behaviour during the late disastrous flood. It will be remembered that these ladies refused to leave their charges, at their imminent personal risk, and instead helped to convey them to the point of comparative safety as the waters rose. The promotion involves a substantial increase of salary. His Highness *has further ordered that all other employees of the hospital who were* on duty on the night of the flood be recompensed with a gift of three months' salary in addition to half the value of any losses they sustained. We learn from the *Times of India* that this act of liberality has been greatly appreciated in the principality.

DERMATITIS DUE TO VANILLA.

To the Editor of THE LANCET.

SIR,—A Hindoo boy, aged 18 years, after handling ripe vanilla pods, [illegible] bsequently for [illegible] a swollen face [illegible] g them. His [illegible] were almost covered with minute discrete pustules, which gave rise to intense itching. His temperature was 101° F. He complained of frequency of micturition with pain or feeling of heat when micturating, which act produced only small quantities of urine

Some other coolies doing the same work, which involves handling the ripe pods of vanilla, have been affected in the same way, but not so *severely. I can find no account in any book I have of vanilla causing* an eruption.—I am, Sir, yours faithfully,

R. F. HILEY, M R.C.S. Eng., L.M.S S A. Lond,
Medical Officer to South Coorg Medical Fund.

Sidapur, Coorg, India, April 14th, 1909

*** Dermatitis among workers in vanilla has been noted before (see THE LANCET, Feb. 16th, 1907, p. 463, and Nov. 24th, 1906, p. 1478), but the exact cause is not settled The eruption has been variously attributed to the principles of the vanilla, to the moulds with which the pods are sometimes covered, and to the treatment applied to the pods to remove such moulds.—ED L.

YELLOW FEVER IN BRITISH HONDURAS IN 1905.

Sir Rubert Boyce's recent visit to Barbados at the request of the C[illegible] report, though printed at the time, was apparently not circulated in this country, nor were *copies, seemingly, sent to the press* This omission was, no doubt, owing to the fact that the report was the property of [illegible] G[illegible] of its p[illegible] only. [illegible] copies for distribution, since one has recently reached us. It is, we think, a matter for regret that this report was not more widely made known when it was first printed. For at that time the text-books and works of reference did not contain full and detailed information concerning the mode of propagation of this dreaded disease, nor did they give a full account of the new methods which scientific observations had shown to be the best adapted for checking its spread. It is true that a small pamphlet was prepared in 1906 by Sir Rubert Boyce and sold for 1*d.*, containing a brief popular description of yellow fever and the way to prevent it. But this small pamphlet was evidently intended for widespread circulation among the West Indian Colonies, in order to familiarise the public with the chief points concerning the malady and its prevention. Such a pamphlet, it is evident, could not take the place of the detailed report in bringing the newly acquired information to the notice of the medical profession in this country. Since 1906 the knowledge of yellow fever has increased, and some of our text-books and works of reference have already been brought up to date, so that the collected facts and opinions which Sir Rubert Boyce put forward in 1906 have lost some, at least, of their novelty and freshness. Still, there is much in the report, as now issued, to interest and instruct the student of modern tropical medicine, notwithstanding that its somewhat belated distribution has, we fear, detracted from its former value.

GERMAN HOSPITALS.

A FREQUENT correspondent writes. "The number of hospitals in Prussia seems to have been rapidly increasing, for while in 1884 there were only 1155, there were 2411 in 1906 The number of beds at the latter date was 138,016 and the number of in-patients 1,036,161, of which 636,149 were males and 400,012 were females. In Saxony there has also been a considerable increase both in the number of hospitals and in the beds, though the gain is not so marked as in Prussia. Thus 93 hospitals with 5374 beds in 1887 increased to 145 hospitals with 10,439 beds in 1906. The Berlin municipal authorities have raised the daily charges which have to be paid by local and parochial bodies sending patients to 3 marks for Berliners and 3 50 marks for those from a distance. Children and adults have to be paid for at the same rate. Other German hospitals are also raising their charges, thus at Kiel 3 50 marks have to be paid for local patients and 5 marks for others."

A NEW DISINFECTOR FOR TELEPHONES.

WE have received from the Telephone Disinfector Company (Messrs. Baer, Bechmann and Co), of 55, Hatton garden, London, E.C., a sanitary appliance for the mouthpiece of telephones. It consists of a metal collar fitting by a spring over the mouthpiece and having hinged to it a disc which forms a cover for the mouthpiece. The central portion of this disc is covered with celluloid on its outer side. When the telephone is to be used this cover or lid is opened by touching a small metal catch, and it is closed as readily by the pressure of the finger and thumb. [illegible] and projects into the mouthpiece of the telephone. It is filled with a brownish crystalline solid substance which has a strong odour of thymol and which impregnates the interior of the mouthpiece, when the lid is closed in the intervals of its use, with a volatile and aromatic disinfectant. Refill cakes of the antiseptic substance are supplied with the instrument We have not conducted any bacteriological experiments to test the efficacy of the appliance, but from the thorough manner in which an obviously effective antiseptic is [illegible] rior of the mouthpiece we consider [illegible] protecting the users of telephones [illegible] blic instruments should be safeguarded from the saliva of their consumptive and syphilitic patrons, and we have seen no apparatus that appears better adapted for the purpose than this. We can also testify from a trial of the appliance that its use does not add to the inconveniences of telephonic communication.

NORTH INDIA SCHOOL OF MEDICINE FOR CHRISTIAN WOMEN.

THE annual meeting in support of the North India School of Medicine for Christian Women (Ludhiana, Punjab) was held on May 5th in the Trinity Church House, Great Portland street, London, W., Colonel Parry Nisbet, C.I E, being in the chair The fourteenth annual report showed that in every department there had been a steady advance during the past year At the hospital 19,671 out-patients had paid 59,800 visits. The average number of beds occupied had been 76, and during the past year 1100 operations had been performed. The number [illegible] who [illegible] spital, [illegible] work, which she said was highly appreciated by the authorities in India. She hoped that one result of her speech might be a much needed increase in the medical staff, which at the present moment was sadly overworked. From intimate knowledge of what was going on, both in the hospital and in the school, the speaker was convinced that the work at Ludhiana presented great opportunities from a medical and from a Christian point of view. The patients came from far distances, even from beyond Lahore. Not only was this true of the poor and ignorant, but even high caste Hindu women had sought medical treatment. As far as was possible, Mohammedans and Hindus were separated in the hospital, and there were also separate departments for medical and surgical cases. Dr. Edith M. Brown, under whose superintendence the work is conducted at Ludhiana, was stated to be exercising a great influence for good among the high caste Hindus in the city. The institution was more than an ordinary mission hospital. It was also an important training place for native Christians whose subsequent work in different parts of the land was of the greatest importance and value. In the training school there were from 40 to 50 students, who were most attentive to their studies. Special attention was called to the need of a large steriliser in the hospital, and in conclusion emphasis was laid on the importance of training girls to go to all parts of India. The work had been repeatedly commended by the Government Inspector-General, but money and workers were needed. At least five or six fully qualified medical officers were imperatively necessary if the institution was to do all that might be accomplished. Dr. Heywood Smith spoke of the missionary aspect of the work, and subsequently Colonel Parry Nisbet, who has had a long knowledge of Ludhiana, expressed his hearty sympathy with the work of the school and hospital. He had often, he said, known medicine to be the handmaid of Gospel teaching. He very cordially endorsed the appeal which had been made for urgently needed financial support and personal service. Miss Mabel W. Brown, 91, College-road, Bromley, Kent, it may be added, is the secretary of the institution.

◆

Feverish.—We recommend our correspondent not to bring the matter before the district council, at any rate until he has been resident in the district longer. The arrangement which he describes is open to criticism as being unfair to the general practitioner, but, on the other hand, the district council is responsible to the public and naturally desires therefore to have the hospital managed by an officer of its own. As the hospital is not at all large, and according to our correspondent "is more often empty than not," the number of fees which the medical officer receives, a part of which is undoubtedly contributed by our correspondent, can be but very small. The second point—viz., that the medical officer of health by being constituted "a fever doctor" may obtain unfair opportunities for increasing his private practice at the expense of his professional brethren—is an abiding grievance under the Notification of Diseases Act since that Act came into force. We are happy, however, to say that the number of cases where this abuse can be shown to exist grows smaller and smaller.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

THURSDAY.

DERMATOLOGICAL SECTION (Hon. Secretaries—Arthur Whitfield, E. G. Graham Little): at 5 P.M.

Dr. Louis Wickham: Demonstration of Radium Therapeutics.

FRIDAY.

EPIDEMIOLOGICAL SECTION (Hon. Secretaries—W. H. Hamer, G. S. Buchanan): at 8.30 P.M.

Papers:

Dr. John Brownlee: Certain Considerations on the Causation and Course of Epidemics.

Mr. M. Greenwood, jun.: The Problem of Marital Infection in Pulmonary Tuberculosis.

N.B.—Fellows of the Society are entitled to attend and to speak at all Meetings.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 P.M., Reception by the President. 9 P.M., Oration:—Dr. H. D. Rolleston: On the Classification and Nomenclature of Diseases, with Remarks on Diseases due to Treatment. Music, Smoking, &c.

CHELSEA CLINICAL SOCIETY, Chelsea Dispensary, Manor-street, King's-road, S.W.

TUESDAY.—8.30 P.M., Annual General Meeting. Election of Officers for the ensuing Session, 1909-10. Dr. Vivian Orr: Intra-spinal Anæsthesia in Surgery.

UNITED SERVICES MEDICAL SOCIETY, Royal Army Medical College, Millbank, S.W.

WEDNESDAY.—8.30 P.M., Major H. W. Grattan, R.A.M.C., and Captain A. L. A. Webb, R.A.M.C.: Demonstration of the Method of Preparing and Standardising Typhoid Vaccine. (Postponed from May 12th).

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

FRIDAY.—8.30 P.M., Adjourned Discussion on Beri-Beri. Communicated by Dr. A. T. Stanton: A Paper on Beri-Beri of Historic Interest, written by Dr. J. Bontius, of Batavia, in 1629.—Captain C. A. Gill, I.M.S. (Lahore): A Note on the Epidemiology of Pneumonic Plague.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. G. Little: Clinique (Skin). 5.15 P.M., Lecture:—Dr. A. Morison: The Treatment of Cardiac Pains.

TUESDAY.—4 P.M., Dr. R. Hutchison: Clinique (Medical). 5.15 P.M., Lecture:—Dr. G. E. Herman: Some Points relating to Ectopic Pregnancy.

WEDNESDAY.—4 P.M., Mr. M. Collier: Clinique (Surgical). 5.15 P.M., Lecture:—Sir Thomas Oliver (Newcastle): Some Unusual Features of Lead Poisoning.

THURSDAY.—4 P.M., Sir Jonathan Hutchinson: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. J. Mackenzie: A Demonstration of Graphic Methods for the Investigation of Cardio-Vascular Conditions.

FRIDAY.—4 P.M., Mr. Stuart-Low: Clinique (Ear, Nose, and Throat).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Lecture:—Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Pathological Demonstration:—Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eyes. 2.30 P.M., Operations.

TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. Carless: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. Sale-Barker: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

2.15 P.M., Special Lecture:—Dr. R. Bradford: Hemiplegia.

SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM, 73, Welbeck-street, W.

MONDAY.—3 P.M., Clinical Demonstration: Dr. H. Campbell.

TUESDAY.—5 P.M., Clinical Demonstration: Dr. J. Mackenzie.

WEDNESDAY.—3 P.M., Clinical Demonstration: Dr. F. Palmer.

THURSDAY.—3 P.M., Clinical Demonstration: Dr. T. D. Savill.

FRIDAY.—2 P.M., Clinical Demonstration: Dr. P. Stewart. 5.30 P.M., Clinical Demonstration: Dr. E. Macnamara.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY.—3.45 P.M., Lecture:—Mr. I. G. French: Tracheoscopy, &c.
FRIDAY.—3.45 P.M., Lecture:—Dr. W. Wingrave: Clinical Pathology.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (17th).—London (2 P.M.), Thomas's (3.30 P.M.), St. George

ond street (9 A.M.),

Ormond street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospital operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

An Oration
ON
THE CLASSIFICATION AND NOMENCLATURE OF DISEASES, WITH REMARKS ON DISEASES DUE TO TREATMENT.

Delivered before the Medical Society of London on May 17th, 1909.

BY H. D. ROLLESTON, M.D. CANTAB., F.R.C.P. LOND.,
SENIOR PHYSICIAN TO ST. GEORGE'S HOSPITAL; PHYSICIAN, VICTORIA HOSPITAL FOR CHILDREN.

MR. PRESIDENT AND GENTLEMEN,—In attempting to discharge the honourable trust laid upon me I shall venture on some considerations on the classification and nomenclature of diseases, and on the diseases directly due to treatment. Definitions are a weariness unto the flesh and the framing of them an intellectual exercise which necessarily often results in a compromise. When a disease (absence of ease) is mentioned we mentally distinguish it from a symptom and from a group of symptoms by the reservation that a disease is a departure from health due to a definite cause, whereas the designations symptom and symptom-complex, or a recognised grouping of symptoms, admit that the underlying cause is not constant. As our knowledge of the causation of disease becomes more complete what was at first regarded as a disease becomes a symptom, and logically a number of recognised diseases are only entitled to be called symptom-groups. Of the two essentials that go to make up our conception of a disease, (i.) the clinical aspect and (ii.) the etiological factor, the first is still the more prominent in our minds. For example, infection with the *B. typhosus* may occur without producing the symptoms of typhoid fever; such a condition as typhoidal osteitis without evidence of previous illness obviously cannot be called typhoid fever. It, however, seems doubtful whether at the present day the word "disease" can be rigidly confined to a recognised group of symptoms due to precisely the same cause, for if this criterion be maintained peritonitis, inasmuch as it may be due to various microbes, is not a specific disease. For ordinary purposes it is at present convenient to retain as diseases what are *really group-diseases; a group-disease* is a characteristic collection of symptoms which may be due to any one of a group of allied organisms. Thus the following allied bacteria, *Bacillus fæcalis alcaligenes*, *B. typhosus*, *B. para-typhosus A*, *B. para-typhosus B*, *B. coli*, *B. paracoli*, have been considered to be capable of producing in man disease indistinguishable from typhoid fever (Stratham).[1] *In the last edition of the official "Nomenclature of Diseases"* [illegible] that paratyphoid fever is now becoming recognised, but the diagnosis can only be made on bacteriological evidence.

Similarly with regard to another common disease the use of the word influenza, of Italian origin, for a familiar train [illegible] as the refuge of those [illegible] or ingenious to arrive [illegible] doubt, much truth in this, but there are practical difficulties in taking up the standpoint that only those cases shown to be infected with Pfeiffer's *Bacillus influenzæ* are entitled to this designation. For it has been proved that among cases clinically alike some show this organism, whilst others do not. In 1905 Bulloch[2] stated that the *B. influenzæ*, common in the early nineties," had become rare and that recent epidemics were caused by various organisms, especially the *Micrococcus catarrhalis*, and that what is clinically called influenza is not one disease but a series of diseases. Lord[3] compared the bacteriology of an epidemic of influenza (1907–08) with a series of sporadic cases in an inter-epidemic period (1902–04) at Boston and found that *B. influenzæ* was present in a higher percentage (25 per cent.) of the sporadic cases than of the epidemic (15 per cent.). He suggested that the cases with *B. influenzæ* should be called "influenza vera," and those clinically alike but bacteriologically different "influenza nostras." This again is logical, but it cannot yet be put into universal practice. No doubt in time the conditions formerly recognised as compact diseases, such as peritonitis, enteric fever, and influenza, will be established in more elaborate nosology as *genera* and will be divided up into their several species. The time, however, for this has hardly arrived, and in practice we must still be content to retain the familiar terms.

The recent multiplication and differentiation of new diseases make it difficult to keep up with modern nomenclature and contrast in a striking manner with the leisurely progress of medicine in the early part of the last century. In 1822 the learned nosologist, Mason Good, secretary of this society and Orator in 1808, says in the preface to his four-volumed work, "On the Study of Medicine": "Whilst a few species of diseases are no longer to be found which are described by earlier writers, a few seem to have supplied their place, which are comparatively of modern origin."

ON THE CLASSIFICATION OF DISEASES.

The classification of diseases more nearly concerns readers or writers of textbooks than those solely engaged in the active practice of their profession; but it is important in connexion with the Registrar-General's returns and of some interest to us, for by the success or failure of our classifications it is possible to arrive at some conclusion as to the extent of our knowledge of medicine and so to estimate how far we are from finality in this subject as compared with sciences such as botany and zoology. There is also another, though perhaps somewhat remote, advantage that might result from the attempt to classify diseases on scientific lines resembling those in the more exact sciences. For just as astronomers and chemists have been able to indicate that a star or an element with certain properties should appear or exist, though at the time unknown, so by employing systematic methods we might anticipate, or, at least, be on the look out for, new forms of disease. Thus, by applying to the consideration of other ductless glands our knowledge that absence of thyroid secretion (myxœdema) and excessive (and? altered) secretion of the thyroid gland (exophthalmic goitre) give rise to diseases, we should be on the watch for a disease due to excessive activity of the islands of Langerhans in the pancreas, which would have the same relation to pancreatic diabetes that exophthalmic goitre has to myxœdema.

The first attempt to classify diseases appears to have been made in 1680 by Felix Plater, who took symptoms as the basis for his classification. About this time Sydenham seems to have suggested that diseases should, like plants, be arranged according to their external features. But it was not until Linnæus showed the way that the hint of the English Hippocrates was taken, and then an enormous amount of labour was expended on elaborate attempts to classify diseases on the lines of the natural sciences. These nosologies—now almost entirely forgotten and buried in the dust of libraries—tabulated diseases by Greek or less often Latin names, the majority of which are quite unfamiliar to modern ears. It is almost pathetic to consider the amount [illegible] work done by the once famous [illegible]), Vogel (1772), MacBride (1772), [illegible] 1810). The importance attached [illegible] a hundred years ago is shown, not only by the number of rival systems, each bristling with criticisms of those already extant, but by the publication of distinct nosologies by such distinguished men of science as Linnæus, Erasmus Darwin, and Thomas Young (1813), the last of whom was described on the inscription on his monument in Westminster Abbey as "alike eminent in almost every department of human learning."

The best known nosological classification was that brought out in 1785 by William Cullen, professor of medicine at Edinburgh. This work, entitled "Synopsis Nosologiæ Methodicæ," was based on a wide acquaintance with previous attempts on the same lines and, evidently stimulated by the success obtained by Linnæus in the natural sciences, aimed at simplifying a difficult subject. Cullen divided diseases into systematic and local, his first three classes, (1) pyrexiæ, (2) neuroses, and (3) cachexiæ, being systematic or general, and the fourth class locales. Each of these four classes was subdivided into orders and these again into sections, genera, and species. Thus in the class fevers under Order III., exanthemata, the genus variola has two species, discrete and confluent. Subsequent nosologists—Young and Mason Good—severely criticised Cullen's confusion of genera and species. Cullen fully recognised the limitations of methodical nosology, and admitted that he could not surmount some of the difficulties by appending, after the four classes, a catalogue of diseases which for various reasons had not been allotted a place in the foregoing nosology. He, however, not unnaturally argued that, just as the earlier attempts at methodical classification in the natural sciences, particularly in botany by Ray, were unsatisfactory, but by subsequent elaboration became successful, so in course of time a perfect nosological classification should be attained.

---

[1] Stratham: Journal of the Royal Army Medical Corps, 1908, vol. xi., p. 351.

[2] Bulloch: Brit. Med. Jour., 1905, vol. i., p. 1044.

[3] Lord: Journal of Medical Research, Boston, 1908, vol. xix., p. 2.

South of the Tweed the most important work on the subject was probably that by John Mason Good, M.D., F.R.S., a Fellow of this society, and one of the most encyclopædic and prolific medical writers of the past, who, as it seems to me, has been undeservedly somewhat forgotten. He has, indeed, sometimes been thought to be an American, because on the title-page of his works he describes himself as Mem. Am. Phil. Soc., and F.L.S. of Philadelphia. He was not on the staff of any hospital, but was in general practice in London, and is said to have translated Lucretius in the course of his walks to his patients. His "Physiological System of Nosology, with a Corrected and Simplified Nomenclature" (1817), which met with the approval of the Royal College of Physicians, was based on symptoms, as were the previous classifications of Sauvages, Linnæus, and Cullen. He considered this to be the only method worthy of attention, and remarks epigrammatically that "of the seat of diseases we often know but very little; of their causes far oftener still less." In this connexion it is interesting to note that after much discussion the committee of the first official nomenclature of the Royal College of Physicians (1869) decided that the proposed classification should be based upon anatomical considerations. Good also wrote a "Study of Medicine" in 1822 in four volumes which, in a posthumous fourth edition (1834), was expanded into five volumes under the supervision of Samuel Cooper, a well-known surgeon to University College Hospital. The classification given in this work differs much from that of Cullen. Good gives six classes:—(I.) Cœliaca; (II.) Pneumatica, Diseases of the Respiratory System; (III.) Hæmatica, Diseases of the Sanguineous Function, including the specific fevers, visceral inflammations, suppurations; (IV.) Neurotica, Diseases of the Nervous Function; (V.) Genetica, Diseases of the Sexual Function; and (VI.) Eccritica, or Diseases of the "Excernent" Function; included under this last head are corpulency, dropsy, tumours, and skin diseases. Each class has orders, genera, and species, as shown by the first page of the table of classification.

Class I. Cœliaca.
    Diseases of the Digestive Function.
  Ord. I. Enterica.
      Affecting the Alimentary Canal.
    Gen. I. Odontia.
        Misdentition.
      Spec. 1. O. Dentitionis.
          Teething.
        2. Dolorosa.
          Toothache.
        3. Stuporis.
          Tooth edge.
        4. Deformis.
          Deformity of the teeth.
        5. Edentula.
          Toothlessness.
        6. Incrustans.
          Tartar of the teeth.
        7. Excrescens.
          Excrescent gums.

This is sufficiently elaborate but his original nosology further gave subheadings of the species, for example:—

O. Dentitionis—
  (a) Lactantium; cutting the teeth or shedding teeth.
  (b) Puerilis; cutting th[illegible]
  (c) Adultorum; cuttin[illegible]
  (d) Senilium; cutting [illegible]

James Copland, *Orator* in 1822, published in the same year an essay on "The Physiology and Pathology of Certain Parts of the Animal Economy, usually denominated the Ganglionic Class of Nerves" (the sympathetic system), in the course of which he arranges diseases in four classes, each divided into orders, genera, and species. The four classes are: (I.) Diseases which consist in a diminution in the natural energy with which the ganglionic functions of an organ or part are performed. (II.) Diseases due to a morbid increase of the ganglionic functions of an organ or part. (III.) Diseases consisting, at one period of their course, of a degree of excitement or reaction of the influence of the ganglionic system, either in an individual organ or texture or more or less throughout the body. (IV.) Disorders which cannot be exclusively arranged under any one of the preceding classes, but most frequently are the consequences of one or more of the diseased actions by which these classes are characterised. Copland's article in the *London Repository, Monthly Journal, and Review* (1822, vol. xvii., p. 369), of which he was the editor, was an abstract of a more detailed exposition which was promised for future publication, but apparently did not see the light. This scheme of nosology has attracted little or no attention, but it is of interest as an early example of the tendency to explain all diseases by the nervous system.

These elaborate classifications were an academic exercise rather than of practical utility. For Dr. William Farr, the acknowledged founder of the science of vital statistics, who compiled the statistics at the General Register Office, Somerset House, from 1838 to 1879, attempted to arrange the death-returns first under Cullen's and later under Mason Good's classifications, but found it impossible to return the diseases under the classes and orders of the nosologies.[4] Interest in nosological systems appears to have died a natural death after Mason Good's works; and systematic works such as Addison's and Bright's "Elements of Practical Medicine," of which the first and only volume, by Addison, was published in 1839, do not appear to deal with the subject. Since then nosological problems have not appealed to English-speaking nations, but in France in 1907 Lancereaux and Paulesco[5] presented to the Académie de Médecine a scheme for the classification and nomenclature of diseases which was referred to a commission[6] who reported favourably and proposed the following somewhat modified classification based purely on etiology:—

1. Diseases caused by physical agents or Physinoses (νόσος, Disease)—
    E.G. Thermonoses = diseases caused by heat.
      Photonoses = diseases caused by light.
      Electronoses = diseases caused by electricity.
2. Diseases caused by chemical agents or Cheminoses—
    E.G. Saturnism, Iodism.
3. Diseases caused by living agents or Bionoses.
    Divided into the animal and vegetable, the latter of course containing bacterial diseases.
4. Diseases caused by moral and intellectual agents or Psychonoses.
5. Diseases caused by nutritional factors or Trophonoses.
    This class, adn[illegible] of the two diatheses scro[illegible]h, appearing under the [illegible]ers a very large field—viz., diabetes, gout, chronic rheumatism, and most tumours.

There is, it must be confessed, a certain fascination about the attempt to fit each disease into its appropriate niche in a formal classification; it recalls our struggles with the "dissected puzzles" of one's childhood. But at present our knowledge is not sufficiently complete to allow a permanent classification to be constructed. In fact, it is probably more difficult now to attempt such a classification than it was in Cullen's time, for though knowledge has advanced it has thereby made our ignorance more obvious, and we realise that any scheme of classification adopted for convenience and practical purposes may almost any day be disturbed by a new discovery.

As the result of research and analysis new diseases are constantly being described, some of which will take an established place in the list of diseases, whereas others are really only aberrant forms of recognised conditions. At the same time, as the outcome of broader knowledge, some conditions previously regarded as distinct are being shown to [illegible] morbid process [illegible] pathological [illegible] distinct from hereditary ataxia but only a form of it; just as tabes and general paralysis are two local divisions of a single morbid process (Mott). Or, to take a comparatively old example, granular kidney, failing heart, and cerebral hæmorrhage are the peripheral results of the general pathological process which begins as a metabolic disturbance and gives rise to an increased blood pressure and so to arterial sclerosis.

[6] [illegible] Révision de la Nomenclature des [illegible]x, Blanchard, Jungfleisch, Reclus,

Again, the various manifestations of well recognised infections, such as tuberculosis and syphilis, in different parts of the body are grouped together in some systematic works on medicine, and the same process might be adopted with regard to pneumococcal, gonococcal, and other infections. This is a logical method of classification, but it can scarcely be adopted in its entirety, for it is often more convenient to classify diseases according to the part of the [illegible] to the underlying cause; thus [illegible] more conveniently classified as [illegible] various causes than as a local [illegible] ith pneumococci, streptococci, *B. coli*. Moreover, a strictly etiological classification might be difficult in cases of mixed infection.

In some instances it is difficult to classify a disease in any [illegible] t present, [illegible] based on [illegible] iderations than to attempt to force all diseases into a rigid scheme, [illegible] ogical factors or on the [illegible] whatever may be said about its limitations, indeed shows a very open mind in the classification adopted; the divisions are: 1. Infective diseases. 2. Intoxications. 3. General diseases not included in the two preceding groups (the anæmias, gout, diabetes, osteo-arthritis). 4. General morbid conditions incident to various parts (malformations, new growths, &c.). And the main part of the work: 5. Diseases of the various systems of the body (nervous system, circulatory, &c.). Some of these groups are, so to speak, repositories into which diseases of doubtful etiology can be left until we have an accurate and exhaustive knowledge of the real causes at work.

The bearing of the classification of diseases on the relations of physicians and surgeons.—Lastly, a few words may perhaps be devoted to a consideration of the change which new methods of treatment have gradually brought about in the broad classification of diseases into those which are medical and those which are surgical. In general practice this distinction is not of quite the same moment as it is in hospital practice and *personnel*. It worked well in the days when surgery could be accurately described as "external medicine," but at the present time it leads to a wholly unnatural division in the treatment of disease. In these [illegible] should be able to [illegible] tart to finish; this [illegible] ists, who though mainly physicians in name are highly skilled surgeons in deed; and much the same is true as regards laryngologists. But the general physician who diagnoses a cerebral tumour, an abscess in the lung, or a renal calculus, is obliged, by his want of equipment, to call on his surgical colleague to complete the cure. The natural outcome of this unsatisfactory state of affairs is that at the present time younger men mainly follow the attractive rewards of surgical practice which now deals so successfully with many diseases formerly within the province of the physician. The experience gained by operative measures so increases the surgeon's powers of diagnosis that he may declare, with the humour which conceals a great truth, that "a surgeon is a physician who can use his hands," and even act on the maxim "Chirurgus sum: nihil medicum a me alienum puto."[7] Not only has the physician's field of activity thus become narrowed but his function as a diagnostician is increasingly restricted by the importance of bacteriological tests and skiagraphy, for the accuracy and value of which he must depend on experts. Further, immunisation has come to take a prominent part in treatment other than purely surgical, and Sir Almroth Wright has predicted that "the physician of the future will be an immunisator"; it must, therefore, be admitted that the pure physician, should he still survive, will be in a parlous plight between the surgeon and the deep sea of bacteriology. The remedy for this, it would seem, is, as foreshadowed by Sir Clifford Allbutt in the preface to his address, "On the Historical Relations of Medicine and Surgery," delivered at St. Louis in 1904, that the existing spheres of influence should be rearranged; [illegible] physician and the gener [illegible] erged and reappear as [illegible] wards for special parts of t [illegible] charge of the neurological [illegible] mpetent to diagnose and treat tuberculous meningitis, a cerebral abscess, a fractured spine, and neurasthenia; the medical officers in charge of the wards for abdominal diseases should be trained to operate when required, and in like manner the medical officers responsible for intrathoracic disease, with which might be combined disorders of the blood and of the ductless [illegible] their cases. [illegible] ch a radical [illegible] ssion, and it [illegible] dually. In [illegible] that present [illegible] ique, would only slowly be replaced by their competent successors; this is undeniable, but in the period of transition the active association of operating assistants would enable the hospital routine to be carried on. Difficulties would also arise in connexion with the allotment of some forms of disease, though in course of time a satisfactory arrangement would, no doubt, be arrived at after due consideration. Possibly surgery of the extremities and removal of superficial tumours, such as carcinoma of the breast, might, together with orthopædics, form a special group; diseases of the kidneys might be associated with diseases of the male genito-urinary organs and gynæcology respectively in the two sexes, and there might well be a department for fevers and for conditions of doubtful diagnosis. The out-patient departments would probably have to be less specialised, so as to insure a general education both for the medical officers and for students. This may seem visionary, but, as has been said, the principle is already in practice in the case of gynæcology and obstetrics.

ON THE NOMENCLATURE OF DISEASES.

The nomenclature of disease is an interesting subject, but in the hurry of the day's work there is little or no time to consider the meaning or the origin of the names of the diseases we are attempting to treat. The nomenclature exists for practical purposes and is convenient but not consistent. Our official nomenclature of the Royal College of Physicians of London undertaken in 1857 was first published in 1869 and is therefore of comparatively recent date. The advantages from a statistical point of view of such a standard nomenclature are obvious; indeed, it was to meet the need felt by the medical department of the army that the construction of such a nomenclature was first mooted. A very definite advantage which should result from such an official pronouncement is the gradual extinction of the numerous synonyms for diseases which often serve only to confuse. By the greater uniformity and accuracy of nomenclature thus obtained conclusions of real value are rendered possible as the result of statistical compilations. The names of diseases have been arrived at in various ways. Some refer to the cause of the disease—for example, alcoholism; some recall t [illegible] c [illegible] c [illegible] does not attempt to describe or explain its nature.

To refer to the last category first. In some cases the popular or folk names of diseases, such as "mumps," "influenza," or "scarlatina," have passed into official use and nomenclature. The name is then merely a label, and its meaning and origin may become obscured and almost forgotten in the dust of years; for example, there is room for some discussion as to the exact derivation of "rickets." Names of this kind, however, are so identified with our conception of the disease that any change is undesirable; they are proper and not descriptive names, and though they have no pretension to scientific exactitude, there is the distinct advantage that they do not pledge us to any special hypothesis. With so many new titles and forms of disease it is a comfort to retain the familiar names and to speak of "measles" instead of "morbilli," and of "German measles" in place of "rubella" or "rötheln."

---

[7] Vide The Annual Oration for 1903, Transactions of the Medical Society of London, 1903, vol. xxxi., p. 332.

Among the names employed as labels are those named after the observers responsible for their recognition. Thus Bright's, Addison's, and Hodgkin's diseases, all emanating from one metropolitan hospital, Guy's—an unparalleled achievement—are fully accepted. In passing, it may be mentioned that in quite recent years the terms "Addisonism" and even "Brightism" have been suggested to describe cases which approach but do not quite correspond to Addison's and Bright's disease. These two words, being in much the same category as "meningismus" and "peritonismus," may offend the exact thinker, though they are convenient as non-committal diagnoses. Besides doing honour to masters in medicine whose names might otherwise cease to be remembered, this pious method of nomenclature recalls the history of the disease and in most cases serves as a guide to the original description of the disease. It seems only right and proper that, if retained, the discoverer's name should be religiously confined to the condition which he described, and not extended to cover some allied and modified condition, or applied to part only of what he described. At the present time there is a decided tendency to restrict the title "Bright's disease" to those medical diseases of the kidney which are regarded as nephritis—namely, acute nephritis, the large white and the contracted white kidney, and to exclude from the category the red granular kidney and the lardaceous kidney. Reference to Bright's paper and plates in Vol. I. of the "Reports of Medical Cases" (1827) shows that with the forms of nephritis just mentioned he included the red granular kidney and, though the words lardaceous or amyloid are not used, the lardaceous kidney. When the original author's name comes to be applied to a condition different from that which he described, it is in most instances time to abandon the patronymic and to employ some suitable synonym if this is ready to hand. It must, however, be admitted that there is something to be said for the use in certain circumstances of the describer's name for incomplete examples of the disease which he described in its most characteristic form; for example, Graves's disease is a much more satisfactory label for an incomplete case than exophthalmic goitre, qualified, to make the description accurate, by the words "without any exophthalmos or goitre."

In some instances the original descriptive title is altogether too cumbrous for ordinary practice, and as a result there is an almost irresistible temptation to substitute "Marie's disease" for "hypertrophic pulmonary osteo-arthropathy," and "Raynaud's disease" for "local asphyxia and symmetrical gangrene of the extremities." This is a point worthy of due consideration by those who have occasion to describe a new syndrome. Had it not been for Ord's suggestion of "myxœdema" for "a cretinoid state supervening in adult life in women," "Gull's disease," which indeed was put forward by Professor Osler in the third edition of his text-book (1898), would probably be in daily use. The adopted name for this disease indeed illustrates another advantage of using the discoverer's name—viz., that it does not commit us to a hypothesis of the disease which may or may not prove to be correct. For "myxœdema" implies an excess of mucin in the tissues which is not constant throughout the disease. It might be urged in favour of employing the discoverer's name for diseases, the exact nature of which is not yet clear, that it is a more or less provisional epithet pending exact knowledge, and that in course of time the name will be changed. To some extent this is coming about; the medical diseases of the kidney are as often spoken of as forms of nephritis as of Bright's disease, and "lymphadenoma" is now the official name of Hodgkin's disease.

Whilst admitting the established examples of diseases named after their describers, there is a considerable reluctance to confer this honour widely. In some instances the plunge has been made by admirers in a country other than that which produced the prophet; thus we owe the title "Addison's disease" to Trousseau, and that of "Stokes-Adams disease" to Huchard, showing that from a medical point of view the *entente cordiale* knows no restrictions of time. In some instances, indeed, the describer's name is applied to the disease only or mainly in the foreign country where the baptism occurred. Thus, in 1815, Joseph Hodgson, who was President of the Royal College of Surgeons of England nearly 50 years later (1864), described dilatation of the arch of the aorta, which he distinguished from ordinary aneurysm, and pointed out that the symptoms were those of heart disease rather than of aneurysm. This condition is known in France as "maladie de Hodgson," but in this country the use of this title would probably convey little and might even lead to the suspicion of confusion with Hodgkin's disease. In Germany infantile scurvy is commonly known as "Barlow's disease" from his full accounts of it first in the Transactions of the Royal Medical and Chirurgical Society for 1884 and again in the Bradshaw lecture of 1894. An objection often raised to the use of an authority's name for a disease is that it may do injustice to the man who really, though perhaps less publicly or fully, first drew attention to it. But it is a question whether the observer who first in point of time notes a certain association of symptoms and morbid changes, or he who more thoroughly works out the details and fully establishes the existence of the disease foreshadowed by his predecessor, deserves the most credit. Advances in medicine, as in other sciences, are seldom due to the isolated efforts of one worker; the same idea is maturing in the brains of several, and it is rare that an affection previously quite unsuspected is brought out in such a complete manner as was the malady rightly known as Addison's disease. Thus, as Bright was the first to point out, the association between dropsy, albuminuria, and renal disease was previously recognised by John Blackall. In some instances this difficulty has been solved by the compromise of blending the later describer's name with that of the original observer. In the case of both Stokes-Adams disease and Cheyne-Stokes respiration, the later and fuller account was published by Stokes. Adams's original description of heart-block in 1827 did not attract any attention until the appearance of Stokes's authoritative contribution in 1846; for this reason, or possibly for euphony, Stokes's name is often put first, although Huchard, who baptised it, called it Adams-Stokes syndrome. It is perhaps a matter for regret that the loyal efforts and distinguished name of the veteran Sir Samuel Wilks are not to be perpetuated in Hodgkin-Wilks disease as a synonym for lymphadenoma; for in 1865 he both fully described the disease and unearthed Hodgkin's original account, which lay buried in the Medico-Chirurgical Transactions for 1832.

Another objection, which, however, is not of much weight, is that an observer may be so active and distinguished that his name becomes attached to more than one disease. Thus we have Addison's disease of the suprarenal capsules, Addison's cheloid (morphœa or circumscribed sclerodermia), and Addison's (pernicious) anæmia; and on the surgical side Pott's disease of the spine, Pott's fracture, and Pott's puffy tumour of the skull, and Paget's disease of bone, Paget's disease of the nipple, and the almost forgotten Paget's "recurrent fibroid" (spindle-celled sarcoma of the subcutaneous tissues). Marie's disease, a synonym which is generally used to describe hypertrophic pulmonary osteo-arthropathy, has also been employed to denote hereditary cerebellar ataxia, spondylosis rhizomelica, and even acromegaly. The last is specially unfortunate because Marie's name is more properly connected with osteo-arthropathy, which he was the first to distinguish from acromegaly. Von Recklinghausen's disease is the name commonly employed to describe the combination of multiple neurofibromatosis, areas of cutaneous pigmentation, and molluscous tumours of the skin; but it is also occasionally applied to a combination of conditions described by him—namely, hæmochromatosis, or bronzing of the skin, cirrhosis of the liver, and of the pancreas terminating in diabetes

On questions of priority national feeling may come in and a disease may have different names in different tongues. The most extreme example of this is probably exophthalmic goitre, which has no less than seven synonyms—Basedow's, Flajani's, Graves's, Marsh's, Parry's, Parsons's, Stokes's disease. Fortunately, some of these, such as Marsh's, Parsons's, and Stokes's disease, are seldom, if ever, used.

Medical men have often described the diseases they suffered from, and in a few instances this double proprietary claim has been recognised by the name of the disease as in Thomsen's disease (myotonia congenita), and Pott's fracture, which this eminent surgeon sustained in 1756. Cruikshank the anatomist and a near relative of his both suffered from certain cerebral symptoms about [illegible] notes; the relative died first and [illegible] with care but apparently did no[illegible] necropsy. With regard to this, Sir Jonathan Hutchinson writes: "If no one has already a better name for the occurrence of sudden epileptoid attacks marked by subjective kakosmia, extreme pallor of face, and a sense of impending death I would venture to suggest that they should be called 'Cruikshank's malady.'"[8] In the case of a few extremely rare and aberrant forms of disease the patient's name has been employed as a label. Thus, Sir Jonathan Hutchinson[9] briefly designates as "Mortimer's malady" what would otherwise be described as "Lupus vulgaris multiplex non-ulcerans et non-serpiginosus" occurring in a patient of the name of Mortimer. He also mentions that Marie referred to two brothers (Hagner), who had been regarded by Erb as probably suffering from acromegaly, as being the subjects not of that syndrome but of Hagner's disease. In connexion with this method of labelling diseases we may recall the baptism of the Flexner-Harris strain of the *Bacillus dysenteriæ*, which depends on its isolation by Flexner from the stools of a patient named Harris. To name diseases after the patients is obviously unscientific, and might if it became prevalent lead to endless confusion. But at present this method of nomenclature is so little employed, and then only for extremely rare diseases which otherwise appear to require very lengthy titles, that it need not give rise to serious anxiety.

The most usual method of describing a disease is to mention the morbid change accompanying or causing the symptoms—for example, cer[illegible] category belong the diseases [illegible] which, though from the time [illegible]mous with "inflammation of," has only acquired this significance in course of years. As the derivation of this familiar suffix is hardly common knowledge, a few words on this point may perhaps be allowed. Mason Good[10] derived *ιτις* from *ἴτης*, meaning hasty, headlong, and attempts to explain its applicability by the sense of "increased and impetuous action" which it conveys. A much more satisfactory derivation and account were given by Dr. T. Buzzard[11] who, twenty years ago, in discussing the question whether the word neuritis rightly described a process of degeneration, quoted an authoritative statement from Professor Kontos of Athens as to the original meaning of words such as nephritis and myelitis: they are really adjectives, the word *νόσος* (disease) being understood; the association with the idea of inflammation is of later introduction and is probably explained by the overwhelming importance of inflammatory diseases of the various parts of the body. Diseases and morbid conditions can thus be very, perhaps too, easily named by adding the feminine adjectival termination *ιτις* to the name of the organ inflamed, and some of the words thus coined have aroused considerable criticism on the ground of their polyglot nature and have been described as barbarous; and it must be admitted that there are objections to "Bartholinitis" (inflammation of Bartholin's glands) or "Wirsungitis" (inflammation of Wirsung's duct). The word "appendicitis," constructed by Fitz in 1886, has survived much opposition, Nothnagel's attempt to substitute "scolecoiditis" (inflammation of the worm-shaped appendix, *σκωληκοειδὴς ἀπόφυσις*) having an historical interest only. It is hardly to be wondered at that "appendicitis" did not appear under A in the New English Dictionary as that volume appeared in 1888, but etymological prejudice perhaps explains why it took 20 years to gain admission into the official "Nomenclature of Diseases" (edition of 1906). In the same way the masculine adjectival termination *ιτης* is found in ascites (*ἀσκὸς* = the belly) and tympanites.[12] Ascites qualifies the word dropsy (*ὕδρωψ*) understood, and means (*ὁ ἀσκίτης ὕδρωψ*) the abdominal dropsy; and tympanites (*ὁ τυμπανίτης ὕδρωψ*) describes the drum-like or windy dropsy. Pneumonia or *the* pulmonary disease is arrived at in a somewhat similar manner, but in the present era of bacteriology it may perhaps seem curious that the title "*the* disease of the lungs" should not have been conferred on the commonest[illegible] culosis, but on acute inflammation.

The pathological method of nomenclatu[illegible] the most satisfactory, for it usually ca[illegible] attempt at diagnosis, but it cannot be un[illegible] as in some diseases the morbid changes respons[illegible] group of clinical symptoms are uncertain or unknown, [illegible] example, no pathological title could be employed for the important and more or less established class of the neuroses. In some cases the most prominent symptom or manifestation of the disease supplies its title, as in aphonia, agraphia, paroxysmal hæmoglobinuria, or hæmaturia. This often answers well, but in some instances, as in whooping-cough, for which we have no alternative name in English now that the words "kink-host," "kink-cough," and "chin-cough" employed in the North are no longer, as far as I know, used, a patient may have the disease, but at some period of the disease may not present the symptom (the whoop) which is responsible for its name.[13]

DISEASES DUE TO TREATMENT.

In considering the worldly rewards of medicine some have been known to complain that it is the only profession, or perhaps in this connexion we should say trade, which is per[illegible]oat. This is a bald, [illegible]ncalculable benefits [illegible] country has played such an important part both in its origination and in its most recent developments—namely, the campaigns against malaria and tuberculosis. True as it is that medicine is always aiming at the extinction of disease, yet in a few instances new morbid conditions have been directly called into existence by methods of treatment which are in every way admirable.

Surgery has not only thrown much light on the "pathology of the living," to adopt Mr. Moynihan's phrase, but it has in a few instances manufactured new diseases. I do not, of course, refer to mistakes in technique which result in failure of the operation, such as peritonitis after laparotomy, infection of the neighbouring tissues with carcinoma during amputation of a cancerous breast, a vicious circle after gastro-enterostomy, Volkmann's ischæmic paralysis due to pressure exerted by splints, or facial paralysis from section of the nerve during removal of a parotid tumour. Probably in the allied category of surgical accidents should be placed cases of pulmonary embolism, often manifested by pleurisy when the emboli are small, after appendicectomy, the necessary manipulation in the course of the operation being sufficient to detach thrombi already formed in branches of the internal iliac and other veins. Again, the occurrence of generalised tuberculosis after excision of tuberculous glands may be explained as the result of handling of glands and the propulsion of their bacilli-laden contents into a vessel. In connexion with this group we may mention unsightly and inconvenient results directly due to operations, such as a ventral hernia after laparotomy, which is a comparatively slight penalty when life has been saved by timely interference, but a somewhat embarrassing sequel of an exploratory operation on a healthy abdomen. Post-operative cheloids probably depend more on the idiosyncrasy of the patient than on the operator.

It is difficult to estimate accurately the influence, if any, of operative interference on chronically inflamed or rapidly growing tissues in the production of malignant disease. In the subjects of multiple exostoses operation on a troublesome exostosis has been known to be rapidly followed by a sarcoma *in situ*. The difficult question then arises whether the rapid growth which necessitated operation was transformed into malignant activity by the surgeon, or whether, as might reasonably be argued, the rapid growth was the first evidence of sarcoma. In the following instance there is some, but not convincing, reason to believe that operative interference excited or accelerated the appearance of sarcoma.

A man with osteitis deformans broke his left humerus, and for eight years afterwards there was some thickening at the site of the union

[13] [illegible] Scotland. It is derived from [illegible] in paroxysms. The first part [illegible]ous with fit or paroxysm."— [illegible]ure, and Treatment of Chin[illegible] somewhat independent in his [illegible]ctly *kind-cough*, means child's [illegible] "Chin-cough" is an ancient English word; its origin is more obscure than that of kink-cough.

In April, 1908, he bruised it and swelling resulted; it was then cut down upon, as sarcoma was suspected, and scraped. The tissue removed was examined by one of the most skilled pathologists in London with a negative result as regards sarcoma. The patient then fell down and broke his humerus at the site of the incision, and shortly afterwards a large fungating mass appeared in the wound. The arm was amputated at the end of June, 1908, and a spindle-celled sarcoma found. Recurrence has since taken place.

Occasionally operative interference may appear, and here I wish to speak with much caution, to arouse latent disease into activity.

A boy in apparently good health underwent a radical cure for a congenital inguinal hernia by my colleague, Mr. C. T. Dent; this was rapidly followed by ascites and eventually—five months later—after several tappings he died comatose, and an extremely cirrhotic liver was found at the necropsy. Here an operation appears, as in rare instances a fall or exposure to cold has been known to do, to have precipitated the ascites of cirrhosis.

As a set off to these accidents due to surgical interference it is only fair to recall the unexpected but undoubtedly good effects that may follow surgical procedures. Purely exploratory laparotomy may exert a surprising curative effect, although the surgeon is not always able to explain the success of his treatment. Numerous examples of the efficacy of "Laparotomy as a Medical Measure" will be found in Sir Frederick Treves's paper with this title in our Transactions (1898, XXI., 220). It is impossible to attempt a full explanation of these results which in itself would provide material for an interesting paper, but some may be due to the perhaps unconscious division of adhesions, some to variations in the opsonic index of the ascitic fluid before and after incision (tuberculous peritonitis), and some to the production of vascular engorgement after the manner of Bier's treatment.

However beneficial in its ultimate results an operation is necessarily to some extent of the same nature as an injury and therefore like results may follow. Thus operation may precipitate traumatic delirium tremens or an explosion of gout in disposed persons. Neurasthenia may undoubtedly date from a necessary operation and the attendant mental anxiety and profound mental disturbance. Insanity may, as Mr. Dent has shown, occasionally follow any surgical procedure, a sequel which is not necessarily due to a hereditary taint or to the anæsthetic; for between the operation and the onset of mental symptoms there is a period of quiescence, thus distinguishing it from the post-anæsthetic insanity which directly follows the narcosis. But as these results are probably in large measure the "after-effects of injuries," so exhaustively considered in the Oration of last year, and are not the outcome of special changes induced by particular operations, it would be out of place to insist on them further.

Of special interest are morbid conditions due to operations which necessitate some radical change in the normal economy of the body—for example, removal of organs, such as the ovaries or testes, exerting a definite influence on the metabolism of the body. The psychical and physical sequels of castration have long been fully recognised and still demand attention both from the practical point of view and from their bearing on the doctrine of internal secretions. In this last connexion the production of cachexia strumipriva by complete thyroidectomy for goitre is of peculiar historical interest. In 1882 J. L. Reverdin described this sequence of events and in 1883 Kocher gave it this name, but considered that it was due to the injuries inflicted on the structures in the neck. These observations paved the way to the recognition of the causal part played by the thyroid in myxœdema and cretinism, for Sir Felix Semon, after reading Reverdin and Kocher's reports, was struck by the resemblance of the condition to myxœdema and put forward this deduction which, like many other original departures, was at first ridiculed. The discussion thus raised, however, led to the appointment of a special committee of the Clinical Society of London and so to the complete proof of his contention. It has perhaps not been sufficiently recognised that years before this—namely, in 1871—Hilton Fagge definitely associated sporadic cretinism or congenital myxœdema with absence of the thyroid gland, and that Gull's description of "a cretinoid state supervening in adult life in woman" was the first clinical account of myxœdema, so that Guy's Hospital had a considerable share in the recognition of these conditions. Here, again, as in the case of other discoveries, the conception was maturing in the minds of several workers. The connexion of myxœdema with thyroidal insufficiency is now such a well-established tenet of our faith that we have already begun to forget the labourers by whom it was established. This consideration may perhaps justify this brief historical digression.

A disease only produced by surgery and already allotted a place in the "Nomenclature of Diseases" (1906), drawn up by a joint committee appointed by the Royal College of Physicians of London, is the (peptic) jejunal ulcer which occasionally follows gastro-enterostomy, especially the anterior operation. The number of recorded cases, about 60, is so small in comparison with the frequency with which the operation has been performed that it would appear that some as yet unrecognised factor is responsible for the production of the ulcer in those cases in which it occurs.

Whilst the treatment of nasal disease, such as removal of polypi, may cure asthma, it is interesting to note that the removal of polypi has been known to be followed by asthma in a person previously free from the disease.

In a few instances ligatures employed in the course of operation may give rise to very definite morbid conditions; it is hardly necessary to point out that stitch-abscesses come under the heading of surgical accidents due to imperfect technique, and that the occurrence of anthrax and tetanus after the use of catgut ligatures, to which attention has been recently drawn (Richardson),[14] is due to infection directly conveyed. As interesting remote effects reference may be made to gall-stones forming on ligatures and to epiploitis. I have collected eight cases in which operations on the gall-bladder for the removal of gall-stones have been followed by a recurrence of the symptoms due to calculi formed in connexion with sutures. Post-operative epiploitis of a very distinctive kind, with the appearance of an abdominal tumour of a puzzling nature, has been referred to the introduction of silk ligatures into the omentum in the course of herniotomy, of which Schnitzler[15] has collected 28 examples, and other operations, for example, after appendicitis. It may occur weeks, months, or even years after the operation. Occasionally hydrocephalus appears after the cure of a spina bifida. Although it is ungracious to look a gift horse in the mouth it does, I believe, happen, though there are few recorded cases, that after the cut facial has been sutured on to the spinal accessory the patient shrugs his shoulders when he smiles.

Though a critical survey of the subject reveals some interesting instances of what may fairly be called diseases due to surgical procedures they are so insignificant in comparison with the incalculable benefits that we owe to the craft of surgery that it would be absurd to exaggerate their importance. It is, however, obviously advisable to consider carefully beforehand what possible bad effects may follow operations which involve radical alterations in the normal relations of the organs of the body.

The effects of *x* rays on the skin and other parts of the body provide an example of a group of morbid changes produced by a new method of treatment. The dermatitis is somewhat analogous to sunburn and the occurrence of malignant disease to Kaposi's disease or the appearance of multiple squamous-celled carcinomas in freckles. Considerable interest attaches to the production of sterility as a result of exposure to *x* rays; this result is probably commoner than is known, for the absence of spermatozoa from the semen thus produced is not accompanied by impotence; Brown and Osgood,[16] indeed, found this condition of unsuspected sterility in 18 persons who had been employed in manipulating *x* rays for half an hour to four hours three times a week for from two to six years—a very startling result. It has been thought that the active destruction of cells induced in the *x* ray treatment of leukæmia may do so much damage to the liver as to give rise to cirrhosis. Mosse[17] has reported a case of lymphatic leukæmia cured by *x* rays in which the patient succumbed a year later to cirrhosis and ascites. Pleurisy with effusion has also been thought to be caused by exposure to *x* rays.

Although it might logically be only consistent to refer to the toxic effects produced by drugs, for example, arsenic and iodide of potassium, a detailed catalogue of these results would not only be tedious but indeed unnecessary, since the effects are examples of well-recognised forms of poisoning.

In the medical [illegible] due to ulcer it [illegible] not even water, i[illegible] apparently because the dry condition of the mouth favours an ascending infection of Stenson's duct. Fortunately, it appears, from the scanty references made to it in medical literature, to be rare; but in 1000 consecutive cases of gastric ulcer treated medically at St. George's Hospital it occurred in 23 cases, or 2·3 per cent; of the 1000 cases 470 were treated by complete oral starvation, and among these there were 21, or 4·5 per cent, cases of secondary parotitis; the two remaining cases of parotitis were in patients on rectal feeding who were allowed to suck ice. It therefore appears that treatment inducing a dry mouth is a definite cause of parotitis.

Great interest attaches [illegible] serum, either normal or [illegible] as in anti-diphtheritic se[illegible] disease," which in a certain proportion of cases follows the injection of a curative serum, are too well known to require any description. They are usually trivial, and even though in exceptional cases they are severe, about 19 deaths being on record, the benefits of serum therapy are so universal that these infinitesimal risks must be neglected. Recently it has been shown that the entrance of an alien serum into the blood gradually produces a condition of hyper-sensitiveness to a further dose of the serum. This condition of anaphylaxis,[18] which is exactly the opposite of immunity, has been extensively investigated in the guinea-pig, and it has been shown that in this animal death with widespread degeneration of the capillary endothelium and hæmorrhages may be brought about by a second injection of horse-serum given after a certain interval (Gay and Southard[19]). The guinea-pigs take about ten days for this hyper-sensitiveness to develop, but in human beings it appears to take longer. Thus if the interval between the two injections is from three to six weeks there is an "immediate reaction," the symptoms of serum disease (rash, &c.) appearing within a few minutes to 24 hours instead of from seven to 12 days as after a single injection. If the interval between the two injections is longer, three months or so, there is an "accelerated reaction" which appears in five or six days. From the large amount of material under their observation Currie[20] and Goodall[21] have collected a considerable number of these reactions, but fortunately it does not appear that the results in man are likely to prove fatal or that they are so severe as in experi[illegible]

[illegible] underlying the positive reaction in the various tuberculin tests In addition, the peculiar symptoms produced in some persons by eggs and usually ascribed to idiosyncrasy are probably examples of anaphylaxis, and it has been suggested that some cases of puerperal eclampsia are of this nature and due to the absorption of the products of autolysis of the placenta.

Whatever the effect on my audience I have not exhausted the subject of the diseases and morbid conditions directly due to treatment, nor is it necessary to attempt to do so, for probably we all make a practice, not only of estimating any good that may have followed our treatment, but also of closely considering what bad results may possibly be due to our active interference.

A Lecture

ON

THE TREATMENT OF CHRONIC DISEA THE HEART.

Delivered at the Medical Graduates' College and Polyclinic on May 13th, 1909,

BY F. J. WETHERED, M.D. LOND., F.R.C.P. LOND.,

PHYSICIAN (WITH CARE OF OUT-PATIENTS) TO THE MIDDLESEX
HOSPITAL, BERNERS STREET, W.; PHYSICIAN TO THE
HOSPITAL FOR CONSUMPTION AND DISEASES OF
THE CHEST, BROMPTON.

GENTLEMEN,—The treatment of well-marked failure of the heart is generally understood by medical practitioners and duly appreciated by patients When there was marked dyspnœa, rapid, irregular pulse, ascites, œdema of the extremities, and other signs of back-pressure, the therapeutic measures which should be adopted are undoubted—namely, cardiac tonics such as digitalis, strophanthus, strychnia, the administration of oxygen, and the like, with due regulation of the diet, removal of fluid by paracentesis or "tapping," suitable purgation, and last but not least—rest. Considerable relief can often speedily be obtained to the above symptoms by the proper adoption of the measures I have indicated, but when the malady has assumed a more chronic condition the perseverance of the medical man and the patience of the sufferer are both severely taxed In the acute stage of cardiac disease all efforts must be devoted to the establishment of satisfactory compensation, the mechanism of the circulation has to be adjusted, mainly by the dilatation and hypertrophy of the ventricles, notably the left. The reserve force of the heart's muscle has to be heavily drawn upon and it is on this factor that the success or failure of the treatment will mainly depend Subsequently, the maintenance of that compensation is equally important and requires a vast amount of care and attention. It is, however, the chronic cases of diseases of the heart to which I wish to confine my remarks this afternoon and to suggest to you the line of treatment which should be adopted, and I shall offer a few practical hints as to the general management of such cases.

The conditions most likely to call for aid are the following: Mitral regurgitation in which there are signs of failing compensation and degeneration of the myocardium, either fatty or fibroid, also certain functional affections of the heart *and cardiac overstrain.* Aortic regurgitation and mitral stenosis less often come under this category, for when compensation fails in these conditions the course of events is much more acute and the symptoms are more of the class to which I referred in my opening remarks

The majority of the patients suffering from chronic disease of the heart in the above sense present evidences of alterations in the walls of the heart. In fact, I would go further than this and say that all patients who show indications of cardiac failure, slight or severe, do so because the muscular power of the heart is not equal to the work which it has to perform. I cannot lay too much emphasis on this point, for in the treatment of these cases all our efforts must be devoted to sustaining the reserve force of the heart's muscle, for if that fails our endeavours will be in vain. In the course of my remarks I shall endeavour to suggest how *this can best be done.*

In the first place I would lay stress on the fact that a thorough coöperation of the patient with the efforts of the practitioner *is absolutely necessary for successful results.* Hence the vital importance that the doctor should obtain the full confidence of his patient. Then the question arises, how much should a patient be told as to exactly what is the matter with him. As a general rule of life, in order that affairs may move perfectly smoothly, complete candour between the operating parties is necessary. For my own part, however, in the treatment of disease I doubt whether this principle always holds. I think it is very questionable whether the exact condition of the heart should be disclosed to the patient. It will in some measure depend upon personality and individual nature. The use of the term "heart disease" to a patient is frequently productive of great depression which it is most important to avoid, whilst the necessary injunctions can generally be given with sufficient emphasis without either minimising the seriousness of the condition or pronouncing words that often to the lay mind sound like a death warrant. Once tell some individuals that they have heart disease and very likely they will never know another happy moment. Another matter on which I desire to lay great stress is that restlessness, depression, and apprehensiveness are characteristic symptoms of failure in circulation, and these may be aggravated if patients are told that organic disease of the heart exists. The state of affairs may be explained to such patients in more diplomatic phrases. For instance, they may be told that as age advances certain physiological changes occur in the tissues, that the organ first to feel those changes is the heart in that it cannot respond to any sudden call as in younger life, hence the necessity of refraining from doing anything that might throw a sudden strain on the heart, such as running to catch a train, walking up hill rapidly, &c. There is among laymen a general impression that "heart-disease" is incurable and in one sense of course this is right. But the physician is aware that if certain maxims are observed in many cases life may be prolonged for some years, for a sufficient number of years, perhaps, to enable the patient to die of old age, whatever that may mean.

Again, if a patient has a murmur, should he be told so? Such a term is likely to be misleading. A murmur is only a sound, to the physician it has valuable indications, but a lay person cannot be easily induced to appreciate these indications, therefore in many cases it may be unwise to make use of the word.

Next as to the principles which have to be borne in mind in actually directing the management of a case of chronic cardiac disease. As I have already said, the essential point is to endeavour to sustain the muscular force of the heart. This may be done (1) by increasing the power of the heart; (2) by taking measures to maintain its nutrition; and (3) by reducing the peripheral arterial tension—i.e., the resistance to the heart.

1. *To sustain the force of the heart.*—This is the point to which main attention is usually directed. The administration of what are known as cardiac tonics is the plan that first suggests itself. It is an error, however, because the heart's action is weak and irregular simply to rely on digitalis and strychnia. Such drugs are certainly useful, so also are strophanthus, convallaria, and sparteine. But all these drugs must be used with caution and discrimination. Employed alone they may sometimes be sources of danger, especially in advanced life, from the power they possess of raising arterial tension. Speaking generally, they are more useful in acute heart failure than in more chronic cases; many idiosyncrasies occur and some patients tolerate some of these drugs badly.

Much more can be done by carefully studying the patient's habits of life. We can do much to increase the cardiac reserve by giving the heart rest. In order to do this it is not necessary to make the patient live the life of an invalid. If we can render the work of the heart more even we shall at the same time increase its power. If, then, we find a weak, irregular pulse, indicating that there is not the calm rhythm that there ought to be, a few tactful questions will frequently enable us to ascertain the cause which has upset the tranquillity of the circulation. In a very large number of instances we shall find that some psychic process is at work increasing the irritability and apprehension which, as I have said, are prominent symptoms of a failing or irregular circulation through the brain. "A regular cerebral circulation is attended with a feeling of security, a failing circulation with insecurity. If we can in any way help our patients to "throw off life-harming heaviness and cultivate a cheerful disposition" we shall do a great deal towards sustaining the power of the heart. This unfortunately, is by no means easy, but by suggesting a regular mode of life we can be of some help. We are consulted by patients in varying classes of life and we must suggest in accordance with circumstances. One of the most difficult is the business man, with myocardial degeneration, who with a large family to support, finds the restrictions and worries of a city life increasingly difficult. In many of these cases it would be most unwise to advise complete retirement from business. But by dint of questions and hints we can often succeed in so rearranging his daily life that the requisite rest can be obtained.

2. *Measures for promoting the nutrition of the heart.*—In order to bring this about we must insure that the coronary circulation is satisfactory. This can best be accomplished by regulating the amount of exercise and rest that the patient takes. The principal object is to stimulate the arterial circulation in the muscles, to hasten the venous currents, and also to promote the passage of lymph through the lymphatic channels. The whole metabolism of the body is thus improved, and the result is eventually shown in a better digestion and general relief of the nervous symptoms. This result may be brought about in the more simple cases by directing the patient to take walking exercise daily, the length of the walk being gradually increased and the gradient up which the patient walks being also raised if possible. At the same time, the patient should pause occasionally and take a few deep respirations. Thus, the lungs requiring more blood, the heart is temporarily relieved. Marked dyspnœa or pain across the upper chest are both symptoms which should receive due attention, being valuable guides to the amount of exertion which may be considered beneficial. For those who cannot take active exercise massage may be adopted, whereby the tendency to stagnant circulation is materially lessened. This measure is particularly useful in assisting to stimulate the coronary circulation in those patients who are bedridden, or compelled to take very little exercise, and on that account tend to impairment of the heart's nutrition and suffer from chilly extremities, feeble pulse, torpid digestion, and passive pulmonary congestion.

3. *To reduce the peripheral resistance.*—Before discussing the mechanical means which have been introduced with the object of regulating exercise I shall briefly consider the third principle which should govern our treatment—namely, the reduction of the peripheral resistance. I do not think that this element has been sufficiently emphasised or understood. It is evident we can attempt to help the heart either by increasing its power or reducing the work which it has to do—that is to say, by reducing the tension in the peripheral vessels. To some extent this may be done by drugs, although recent investigations have shown that the vaso-dilators as a rule only cause very temporary lowering of the tension, and are more of use when a temporary relaxation of the walls of the vessels is required than when a prolonged effect is required. Thus the vapour of amyl nitrite is very rapid in its action, and so is useful in an attack of angina pectoris, when immediate and decided action is necessary. The same remark applies to nitroglycerine, usually prescribed in the form of liquor trinitrini or in tablet form. For a more prolonged action nitrite of sodium will be found satisfactory. I have also obtained good results from the administration of iodide of potassium (from three to five grains) with the bicarbonates of sodium and potassium. These may be combined with the cardiac tonics, strophanthus being given if the tension is inclined to be high.

I have now to consider mechanical methods of treating chronic heart disease. I would here speak with due caution, basing my remarks on my own experience as well as on discussions which have taken place from time to time in the medical press and at the societies. These methods may be divided into treatment by baths and by exercises. I will first speak of the baths.

Certain spas, notably Nauheim, have derived great reputation for the treatment of cardiac affections. Indeed, at one time there was almost a tendency amongst the public to think that if anyone was a sufferer from heart disease he must go to Nauheim. Fortunately, that feeling is not so strong as formerly. Personally, I believe that certain cases may derive considerable benefit from a visit to Nauheim or other spa where waters highly charged with carbonic acid may be obtained. There is a decided limitation, however, to the cases which may benefit, but perhaps my reasons for expressing these opinions will not coincide with those of other physicians. I have already laid stress on certain symptoms which cause such distress to some cases of chronic heart disease—namely, restlessness and apprehensiveness. The mere fact of "doing something" for these patients, the knowledge that some active measures are being taken other than taking drugs, have a very beneficial effect on some individuals. If we can succeed in calming their apprehension and removing them for a time from their gloomy introspective habits we shall have done great service. At Nauheim various strengths of baths are given and it gives a great sense of encouragement to the patient when he is allowed to go from a weak bath to a strong one, especially when he is immersed in the "Strom Bad" he feels he is indeed making progress, and the nervous symptoms are accordingly relieved. Further, the temperature of the bath tends to produce dilatation of the peripheral vessels and so may relieve the heart in that way. For my own part, I also believe that the effect of the carbonic acid at a high pressure increases the dilatation of the vessels and that an effervescent bath has rather more effect than an ordinary bath at the same temperature; I admit, however, the mental processes may again play an important part. On getting out of the strongest bath the skin is certainly red, and, as I say, I believe this stimulation has some real though perhaps slight effect. Next as to the various forms of graduated exercises that have been introduced. The three chief varieties are well known to you—the hill-climbing of Oertel, the mechanical contrivances of Zander, and the resistance exercises of the brothers Schott. It is, indeed, important to remember that in the majority of cases of the class of diseases I am now considering a certain amount of regulated exercise is demanded. It is a great mistake for these patients to consider themselves as bed- or sofa-ridden. But the exercise must be carefully controlled. Generally a few simple precautions are all that is necessary, but in some instances a regular course is of benefit, for the same reasons which I gave in the case of the baths, firstly, because it proves to the patient that "something is being done" for him. The consciousness of this is of surpassing benefit to some minds. Secondly, because a muscle in action requires more blood than a muscle at rest. I consider that muscular action properly controlled is useful in some of these cases. For choice I should choose either the hill climbing or the resistance exercises as being the most easy of application. In addition to the movement of the muscles of the trunk and limbs, the deep respirations which are directed to be taken attract more blood to the lungs and so add to the relief experienced by the heart.

I wish entirely to dissociate myself from the practice sometimes adopted of taking diagrams of the tracings of the area of cardiac dulness before and after the baths and exercises. As far as I am aware these tracings have never been scientifically proved. In percussion the personal element enters strongly—perhaps that may be the explanation. It is quite possible that at the end of a course of treatment the heart may be less dilated than before, but I have never been able to determine any alteration after single baths and exercises. Here again I am only expressing my own opinion; other observers may entirely differ from me. To express the matter in a few words, I consider that the benefit which some individuals experience by a visit to Nauheim or other similar resort is due very largely to the regular *régime* under which they are placed, and but little to the actual potency of the waters.

Can similar results be produced at home by artificial baths? My own experience has not been favourable in this respect. If the patients could be induced to undergo precisely the same *régime* as at the spas I think much might be done, but the arrangements in this country do not permit of it unless one of the English watering-places is visited, and even then, much as one dislikes to say it, with one or two praiseworthy exceptions the necessary support is not afforded by the local and hotel authorities to the medical men. The fault does not lie with the medical profession but with those who are responsible for the general social arrangements. Moreover, the mere fact of being sent to a foreign spa, with all the changes in diet and mode of life, the interest of watching foreign folk and customs, adds to the moral effect of the treatment which, in my opinion, has such an influence on the mental attitude of sufferers from chronic heart disease.

Closely allied to the mechanical treatment is the diet. This should be simple, attention being duly paid to the state of the digestive organs. When the gastric circulation is disordered faulty digestion must follow. But beware of the usual "invalid" diet! When will it be fully recognised that much of the carbohydrates is digested by the ptyalin in the saliva? What can be more favourable to fermentation in the stomach than to give starchy pultaceous food which is designed to be
without mastication and without proper
saliva? A certain amount of saliva is und
but probably not in sufficient quantity to
carbohydrates which lie unaltered in the
tendency to undergo undesirable fermenta
substances then should be given which can be
masticated. Starchy foods should be given in the form
biscuits or "flowered" potato and directions should be given for thorough mastication. Fish, chicken, boiled mutton, and other digestible foods may be given, preferably in small quantities, and the meals may
wiches of fresh potted meat or
essences in strong solutions.
be as dry as possible, the liquid being taken at the end of the meal.

Time will only permit of a few remarks on symptomatic treatment. The most important condition probably is insomnia. Want of sleep is a common symptom in heart failure, and if rest be procured great relief will often follow. Simple means, such as change of position, bathing the face with warm water, a handkerchief over the eyes, or a little warm drink may be tried. Frequently, however, a hypnotic will be necessary. After trying many, I have found chloralamide dissolved in rectified spirit the most favourable, commencing with 20 grains and pushing it up to 70 grains if necessary. Veronal in 2 to 7 grains may also be tried, but must be given with caution. Sulphonal or trional I have not found so good. Paraldehyde is sometimes useful. In some instances opium or morphia must be resorted to, the chief contra-indication being pulmonary engorgement.

Palpitation.—This symptom may be caused by the cardiac condition or by digestive disturbance. Strychnia, nux vomica, or digitalis may be necessary, but in many cases the bromides are the most useful drugs.

Indigestion.—If this cannot be remedied by diet, relief may be obtained by the use of drugs as usually prescribed in dyspepsia. If there is undue fermentation I have found taka-diastase a useful preparation. Bismuth in the liquid form, given with nux vomica, may also be tried.

By judicious employment of the methods which I have described in this paper much may be done to relieve the lives of those who are the victims of chronic cardiac disease. Hope springs eternal in the human breast, and although some of our patients may have given way to despair in the belief that their lot can never be improved, yet by perseverance in the directions which I have indicated the lives of such patients may not only be rendered endurable but eventually they may enjoy an immunity from suffering and discomfort which is, indeed, to them a consummation devoutly to be wished.

NOTES ON THE EFFECT OF RADIUM IN RELATION TO SOME PATHOGENIC AND NON-PATHOGENIC BACTERIA.

By C. E. IREDELL, M.D. Lond., M.R.C.P. Lond.,
SURGEON IN CHARGE OF THE ACTINO-THERAPEUTIC DEPARTMENT, GUY'S HOSPITAL;

AND

E. P. MINETT, M.D., D.P.H.,
ASSISTANT BACTERIOLOGIST, GUY'S HOSPITAL.

THE physical properties of radium are of considerable importance, both from a clinical point of view and in their relationship to x rays, it being a substance which is constantly giving off emanations without appreciably losing weight. These emanations are comprised, as far as is at present known, of three kinds of rays, named respectively α, β, and γ. The α rays consist of particles of matter of the same size as an atom of hydrogen, and travel at one-twentieth of the velocity of light, these properties being similar to those of the anodal rays produced in an x ray tube. The β rays are from 1000 to 2000 times smaller than an atom of hydrogen, and travel with the same velocity as light, these properties being similar to those of the kathodal rays of the x ray tube. Both α and β rays are deflected by a magnetic field. The γ rays differ from the above in not consisting of particles of matter but of vibrations of the ether of very short wave length, nor can they be deflected or reflected by any known means, travelling always in a straight line. No known substance is absolutely opaque to them, resembling in this respect x rays. The α rays have very little power of penetration but a rather severe effect on the skin, whilst the γ rays are very penetrating but damage the skin very slightly, the β rays occupying an intermediate position in both respects.

Radium when employed for therapeutic purposes was formerly used in powder or small lumps inclosed in either a glass or aluminium tube. This method has now been superseded by spreading the radium, in the form of sulphate, over the surface of a flat metal disc and then fixing by means of a hard varnish.

The earliest form of varnish was employed by Danlos in 1905, but the modified form as used and described by Danne is now commonly used. The sulphate is preferred to the bromide for the form of application on account of its being insoluble, whereas the bromide being readily soluble is more liable to loss and damage in use. When used in the form of bromide it is best used pressed in the thinnest possible layer between a metal back and a thin aluminium or mica window as described by Macleod, who also sums up the advantages of the spreading and varnish method as follows: 1. That by it practically all the rays from the radium are available, the less penetrating rays not being intercepted by the glass, mica, or aluminium window of the older applicators 2. That in a given quality of radium a much larger radio-active surface is obtained over which the radio-activity is evenly distributed. And it has been estimated that 1 centigramme of a radium salt of an activity of 100,000 has approximately the same effect on tissue as 5 centigrammes of a salt of an activity of 600,000 collected in a small mass in a glass tube.

Radium is now being extensively used at the Radium Institute in Paris for the treatment of various malignant growths, such as epitheliomata, rodent ulcers, &c., and has also been favourably reported on in treatment of angiomata by Wickham and Degraise. With regard to the action of radium on the lower forms of life, ferments, &c., the following is a brief summary of the principal results recorded.

M. Dauphin, working on the effects of radium emanations on the various moulds, concludes that "the rays of radium stop the growth of mycelium of the Mortierella and prevent germination of the spores. This action is, moreover, chiefly paralysing; they cause the appearance of real cysts in the interior of the filaments, evidently organs of defence." He also concludes that spores and mycelium submitted to the action of the radium are not killed, but that they are in a latent state of life and when replaced in normal conditions can once more germinate or continue to develop afresh.

Victor Henri and Mayer found that the radium rays rapidly destroy the activity of the ferments emulsin and tyrosin.

Wilcock later confirmed their results with regard to pepsin, trypsin, and ptyalin, but states rennin to be exceptionally resistant; but Schmidt Nielsen found rennin to be slightly weakened.

Fenton has shown that radium rays produce H_2O_2 in water and Vanderelde showed that these ferments are not only immune to, but more active in, presence of H_2O_2.

Ch. Bouchard and Balthazard working with various bacteria state that when exposed to the emanation from 0·0006 of a milligramme of radium for one hour these organisms suffered a reduction in colour, virulence, and showed an increase of involution forms. They also showed that when the emanations from 0·003 of a milligramme of radium are applied to a growth of *Bacillus pyocyaneus* the pigment (pyocyanin) was still diffused into the media, and further that the colour of *Bacillus prodigiosus* was unaffected. In the case of a stab culture apparently radium only affects the surface colonies and does not penetrate.

A large quantity of radium has recently been acquired for Guy's Hospital, and the treatment of cases is now in active progress; and with a view of ascertaining the action of radium on the various bacteria, both pathogenic and non-pathogenic, advantage was taken of the presence of the radium above alluded to in the hospital for one of us to conduct the following experiments in the bacteriological laboratory by the kind permission of Dr. J. W. H. Eyre. Our object was to determine the direct action of this substance on various cultures and organisms as regards their capacity for growth, chemical properties, staining reactions, and also motility, after being exposed for varying periods of time to the direct action of radium emanations.

The first experiment was conducted with a view to ascertain the capacity for growth of organisms after exposure to radium rays, and also to observe any possible effect on the media used. Plates of nutrient agar were poured and dried for one hour in the incubator at 42° C. After cooling, a loopful of a 24-hours broth culture of *Bacillus pyocyaneus* was spread evenly over the surface of each of these plates. The radium was now applied directly to the surface of the inoculated media, for 10 minutes, 20 minutes, and 60 minutes respectively. After exposure a sterile platinum loop was rubbed over the exposed area and a sloped tube of nutrient agar was inoculated with the loop. Both the tubes and plates were now inoculated for 24 hours at 37° C. and examined for growth, the exposed and unexposed areas on the plates being carefully compared; three cover slides were prepared from the exposed and unexposed areas on the plates, also from the tube growth. These were each stained by weak carbol-fuchsin, carbol-methylene blue, and by Gram's method. After careful comparison, no difference whatever could be detected in the capacity of the organism to take the various stains after exposure, its capacity for growth and reproduction was unimpaired, as also was the amount of pyocyanin diffused into the media. A virulent culture of anthrax, only two strains removed from the human body, was also inoculated in a similar manner to the above, and no difference whatever could be detected in the growth before or after exposure. In addition, portions of a plate showing luxuriant growth were exposed to the radium rays for 30 minutes and 60 minutes respectively. These were afterwards examined for capacity to grow and multiply in comparison with the unexposed areas and found to be identical. Cover slides from the cultures before and after exposure were also stained with a differential stain to demonstrate spore formation, the only difference observed being that after 60 minutes' exposure to radium it was thought that the organism showed a slightly increased tendency to spore formation.

Staphylococcus aureus was also investigated in a similar manner and was found to be unaffected as regards its capacity to grow, multiply, and stain evenly and readily after exposure to radium for periods ranging from 15 minutes up to 60 minutes, it being impossible to detect any difference whatever. Various non-pathogenic organisms were also investigated, such as *Bacillus subtilis*, *Bacillus megatherium*, &c., and all were found to be unaffected as regards capacity for growth, staining reactions, and in some cases motility.

Bacillus coli communis, on account of its importance in bacteriology, was investigated fully as regards growth, staining reactions, and motility after exposure to radium for various periods of time, such as 30 minutes, 60 minutes, &c. One culture was exposed to radium for 17 hours and found to be unaffected. In addition, the fact that its biochemical character was unimpaired was demonstrated both by planting colonies after exposure to radium for various periods on to Conradi and Drigalski litmus, lactose plates; by planting into bile salt litmus broth, and observing acid and gas formation; also planting on to mannite neutral red nutrient agar plates. In every case parallel cultures of the same strain of *Bacillus coli communis* not previously exposed to radium were made and carefully compared, but after examination by three independent and competent observers all were agreed that no change whatever had taken place as a result of the exposure to radium emanations.

The influence of radium rays on the motility and agglutinating powers of organisms was investigated in the following manner. A loopful of a young and vigorous strain of *Bacillus typhosus* was planted into sterile nutrient broth. This was then incubated at 37° C. for 18 hours. At the end of that time a loopful of the culture was examined and was found to be actively motile. To exclude the presence of clumps as a source of error in the subsequent observations a few sterile glass beads were added to the broth culture and placed in an electrical "shaker" for a few minutes. On again examining a hanging drop the organisms were found to be discrete, actively motile, and absolutely free from clumps. Six hanging drops were now prepared from *the same culture and compared at once for motility, freedom* from clumps, &c. The controls were labelled Ca, Cb, and Cc, and the others 1, 2, and 3 respectively. They were now exposed to the radium emanations for 15 minutes, 30 minutes, and one hour respectively; then again carefully compared with the 'control' at the end of their respective periods of exposure. This experiment was repeated several times, and the collective results noted. It was found that in the case of *Bacillus typhosus*, in most of the samples examined, a slight increase in motility was observed at the end of 15 minutes, but after 30 and 60 minutes' exposure no difference whatever could be detected between the organisms under observation and the control. This is most interesting, as Fenton has shown that radium rays produce hydrogen peroxide in water, and it would here at least have been reasonable to suppose that, even if the radium rays themselves did [illegible] the *Bacil* [illegible] done so. [illegible] if at all in such a short time; consequently being so very dilute the effect was to stimulate the organisms rather than act as a germicide. Cultures of *Bacillus coli communis* were also examined for decrease in motility, if any, a rather more actively motile specimen than usual being used. But none whatever could be detected. Various non-pathogenic organisms were examined at various times and in a similar manner, but in every case the result was negative.

THE THERAPEUTIC EFFECTS OF RADIUM EMANATIONS IN SOME DISEASES OF THE SKIN.

BY H. RADCLIFFE CROCKER, M.D. LOND., F.R.C.P. LOND.,
PHYSICIAN FOR DISEASES OF THE SKIN AT UNIVERSITY COLLEGE HOSPITAL.

WHILE much has recently been written on the effects of radium on skin diseases, especially when spread and set in a thin layer, I am not aware of any publication on the effects of radium emanations in skin diseases, and the following observations will therefore be of interest. At the beginning of 1906 Sir William Ramsay was [illegible] with these emanations, which are [illegible] gas from a solution of radium [illegible] quantity as regards bulk, but in [illegible] and in some cases very powerful effect. Thus the amount given off from 150 milligrammes in 24 hours was estimated by Sir William Ramsay to be about the fortieth of a large pin's head. At the same time some of the water is decomposed into its component pa[illegible] the three gases are conduc[illegible] bulb where by an electric [illegible] are reunited into water and [illegible] solution and after dilution up to two cubic centimetres the [illegible] d be [illegible] two forms, locally and by subcutaneous injection. For the local application I asked Sir William Ramsay to have the solution of the emanation diffused through a weak gelatin jelly. The tube containing the freshly prepared jelly was immersed in warm water to melt it, the tube broken, and the fluid applied to the surface to be treated and covered first with muslin and then with lead foil which was bandaged on. The first case to which it was applied [illegible] who for the previous [illegible] some eczema of the fin[illegible] fire engine. It was in the form of horny scaling of the backs of the fingers of the right hand chiefly but slightly on the left; *when the hands were in contact* with water the skin became softer and almost "raw." In other ways he was a healthy man. The patient stated that *he had a constant succession of attacks*; [illegible] hand was bad, then it would take a mo[illegible] and then it would break out again. The[illegible] were wrapped up for a week in a glycerine [illegible] lead solution without any marked difference. [illegible] 1906, the right index finger was treated with radi[illegible] emanation solution as above described for one hour, and the middle finger in the [illegible] lead being continue[illegible] the 19th the skin on [illegible] and the horny thicke[illegible] was peeling off, leaving the skin beneath healthy looking. The lead-treated fingers, although showing some improvement, were much behind those treated with radium. On the 23rd the relative improvement was maintained and gelatin without radium emanation was applied to the lead-treated finger to eliminate any source of error in the comparison. On the right fourth finger radium emanation was applied for four hours, and three days later the skin was pale and the diseased epidermis exfoliating. The second finger, which had had the emanation for two hours on the 19th, was better than the index which had had it for one. On the 30th the index, middle, and fourth fingers again had the emanation for two hours. On Feb. 6th there was no marked difference except that the middle finger was no longer painful. The application was repeated for two hours. On the 9th there was a thick layer of scales on the treated fingers but when this was picked off the skin beneath was pale. On the 13th the application was kept on for 12 hours and on the 16th the improvement was much more marked. The greater part of the thickened skin had exfoliated and where this had occurred the skin appeared normal. The contrast between the fingers treated and the ring finger which had had no emanation was very marked. On the 27th the improvement was maintained and the patient was discharged from the hospital.

The case showed first that radium emanations can be used with beneficial [illegible] secondly, that [illegible] *not only safe* [illegible] applications at first employed for fear of evil results from an agent of unknown power. In the next case, therefore, a girl, aged 12 years, with palm-sized hard patches of psoriasis on the knees, the application was made more boldly and she was treated as an out-patient. The procedure was on the same lines and the patches were completely removed and the knees remained well, speaking from memory, for a year or more.

In the two following cases the radium emanation was dissolved in 2 cubic centimetres of distilled water and injected subcutaneously in the interscapular region. The first, a man, aged 30 years, who had been in the Marines from the age of 16 for 12 years, having gained his early admission by saying that he was 18, had seen service in the Mediterranean, off the west coast of Africa and Ascension Island, Spain and Portugal. He had some granulomatous tumours which were diagnosed as due to mycosis fungoides, and although, contrary to his statements, there was reason to believe that there was a syphilitic element, the fact which is important as regards the radium emanation remains that he had granulomatous tumours which yielded to a great extent to the radium injections. The man had been in the University College Hospital in June and July, 1905, and most of the tumours had yielded to x ray exposures He was readmitted in February, 1906, with nodular tumours from a hazel nut to a walnut in size, chiefly in the scapular regions, especially on the right side The first injection was made on Feb. 9th in the middle of the vertebral border of the right scapula. The injections were repeated weekly, or nearly so, until May 4th, 13 injections in all. There was slight aching for a short time after the injections, otherwise they gave very little inconvenience, and under their influence the tumours had in great part cleared up and the arms also had improved, but all the lesions had not entirely disappeared.

The second case, a woman, aged 32 years, was an indubitable and uncomplicated case of mycosis fungoides. She first came under my notice as a private patient in June, 1907, the disease dating from June, 1906. As she could not afford x ray treatment and the disease being already in the tumour stage she was admitted into University College Hospital where she was treated for seven weeks with the x rays with great benefit, most of the tumours disappearing. She subsequently attended irregularly as an out-patient. After being absent from illness for some months she was re-admitted on July 29th, 1908, on account of numerous fresh tumours, very large and fungating on the buttocks and numerous smaller ones scattered about the body and limbs. The treatment was carried out by Dr. George Pernet, then assistant medical officer in the skin department, and in full charge during my absence on holiday. The following is an abstract of his notes. On August 21st the injections were commenced in addition to x ray exposures for the buttocks, the emanation being collected in 24 hours from 231 milligrammes of radium and injected under the left scapula. On August 25th it was also applied locally in gelatin, covered with lead foil as before described, to a group of granulomata on the flexor surface of the right forearm. It was removed after 24 hours and the surface of the granulomata was covered with blackish looking epithelium. There was no pain felt. On the 28th it was noted that apparently as the result of the first injection there was more discharge from all the growths. A second injection was made and on Sept. 1st the discharge was still very abundant from all the open tumours, especially in the axillæ, and she felt more comfortable there; a tar bath also gave her relief. A second local application was also made in the same place. A third injection and local application were made on the 8th. As a result of the latter there was a great deal of discharge at the site of application and some redness and soreness but no pain. The tumours were flatter. There was also some flattening of the tumours of the upper part of the back near the injection site and profuse discharge everywhere. A fourth injection with a similar result was made on the 18th.

Case 3 was a private patient, a lady, who had suffered from a chronic scaly eruption extending all over the covered parts of the body and limbs which had for many years defied medication and spa treatment of all kinds from the principal dermatologists of England and the continent. The eruption had, however, yielded to the x rays, but only at the parts immediately exposed to them. In the hope that the injection of radium emanations might have a wider influence than the x rays she consented to have the experiment made. The details of the disease are published under Case X. of my article on Xantho-erythrodermia Perstans.[1] The first injection was made on May 11th, 1906. On the 18th the site of the injection was sore, swollen, and hard; the same effect was produced by the second and third injections, but the fourth and fifth were injected somewhat deeper and no induration followed, but in the three following made as deeply there was some induration, but less than the first two. On July 3rd, when the eighth was given, there was no material change in the skin condition, but on the 23rd there was considerable change for the better, much of the eruption round the site of the injections having cleared but not completely. On the site of the eighth injection on the left side there was a red raised swelling one inch in diameter, tender but not excessively so. She was not seen again until Oct. 25th, and it was then noted that the skin was paler in the area of injections, but the results were not striking enough for the injections to be continued. On Feb. 25th, 1908, the next time she was seen, the area in which the radium injections had been made was quite clear for a space including the whole scapular region and that of the left deltoid.

Few as these observations are they show that radium emanations have very decided effects, whether used locally or subcutaneously, on chronic inflammations of the skin on the one hand, and on granulomata on the other, and while nothing revolutionary has been or is likely to be obtained from their use, a good case for further investigation has been made out if, and when, as we are promised, a large supply of radium will soon be available in this country to afford these emanations in sufficient quantity daily; radium being like a milch cow, able to give a daily supply for a considerable period, though again like that useful animal, it requires intervals of rest also. An interesting point for investigation is, which of the above effects are due to the alpha and which to the beta and gamma rays. We know that as radium is usually applied, the alpha rays can be screened off by glass, mica, and even paper, leaving nearly all the beta and gamma rays, which have proved so valuable for rodent ulcers in spite of some *ex cathedra* statements to the contrary, while, as Wickham has shown, prolonged exposures through lead-foil are also valuable, the gamma rays being then the chief agent. I am not aware of any experiments on the alpha rays alone, for they are so easily cut off that isolation is difficult. Even in the gelatin solution Sir William Ramsay estimates that probably 50 per cent. are lost, while all the beta and gamma rays would be available. On the other hand, in the subcutaneous injection of a simple solution in water of the emanation all the rays could take effect. The painful swellings produced in one of the cases by subcutaneous injection were absent in the other two, and can be diminished by the injections being deeply made; still it is a drawback which must be faced as a possibility and would tend to restrict the hypodermic use to diseases of severity or resistance to other therapeutic measures; but as regards the local application no trouble of any kind was observed. It was hoped that opportunity for further observations would have been afforded, but so large a quantity of the radium salt is tied up for a considerable time to obtain the emanations that this has not been the case.

Harley-street, W.

THE ELECTRO-CARDIOGRAM OF MAN AND OF THE DOG AS SHOWN BY EINTHOVEN'S STRING GALVANOMETER.

BY A. D. WALLER, M.D. ABERD., F.R.S.

A VISIT to Leyden during the Easter vacation and a review of the extensive collection of human electro-cardiograms gathered together by Professor Einthoven during the last ten years have very materially assisted me to a general understanding of the information he has obtained by this method of investigation. My own observations in 1887 were limited to the demonstration of the facts and of the favourable and of the unfavourable physical conditions of the demonstration in accordance with the position of the heart, and I certainly had no idea that the electrical signs of the heart's action could ever be utilised for clinical investigation. Indeed, while even now the points that appear to me to be of principal interest are in the first place the bare fact that by leading off from the extremities of any man, woman, or child the electrical effects accompanying the heart beat can be seen and photographed, and in the second place the general conclusion derived from a comparative study of electro-cardiograms to the effect that the normal progress of muscular contraction is essentially similar in man and in the dog and in the frog, I am constrained to admit that Professor Einthoven's results, obtained with the extraordinarily *sensitive* galvanometer he has invented, show that the method is capable of giving real information unattainable by any other means, besides bringing out with a clearness and distinctness unapproachable by any other instrument the actual details of the normal electro-cardiogram.

In my first experiments I only noted a double positive effect with each ventricular systole, the first effect being small and of rather doubtful direction, the second being longer and more prominent and simultaneous with the ventricular systole. These are the waves R and T of the series of five waves P, Q, R, S, T, that Einthoven distinguishes (Figs. 1 and 2) in the normal electro-cardiogram. To recognise these points it is necessary to study the typical electro-cardiogram of the *human* subject with, e.g., the right hand and the left foot placed in connexion with the two poles of Einthoven's galvanometer. With the instrument at my disposal in 1887—Lippmann's capillary electrometer—the first wave P, which is due to the auricular contraction, was altogether invisible and the two negative waves Q and S immediately preceding and succeeding the first ventricular wave R could not be distinguished. Einthoven now shows that in cases of hypertrophy of the right ventricle resulting from mitral regurgitation this first ventricular wave R is considerably increased, whereas in cases of hypertrophy of the left ventricle resulting from aortic regurgitation R is reduced or actually of reversed direction, downwards instead of upwards. The fact is unexpected, but quite clear and

characteristic, while by no means easily explained. If upward movement signifies negativity of the base of the heart downward movement signifies negativity of the apex of the heart, and it is difficult to understand why such a reversal should be an effect of mere hypertrophy of the ventricle. Another change pointed out by Einthoven as being characteristic of mitral stenosis is, perhaps, easier to account for [illegible] icular wave P signifying [illegible] the auricular contraction [illegible] " where two auricular beats occur to each ventricular beat, or where the auricular and ventricular beats are completely dissociated; the abnormal (allorhythmic) abortive beats of an unfilled heart leading to dropped pulse beats; various forms of atypical heart beat with or without the production of an arterial pulse are all very clearly brought out in Einthoven's electro-cardiograms, and throw light not otherwise obtainable upon obscure clinical manifestations of disorderly cardiac action. I do not however imagine, nor I believe does Einthoven, that the string galvanometer, however useful and even necessary it may be in the physiological laboratory, is likely to find any very extensive use in the hospital as affording means of physical diagnosis more searching than those in daily use. It can at most be of rare and occasional use to afford a concrete graphic record of some rare anomaly of cardiac action, as it has already in the hands of Einthoven, Lewis, and others served to bring into clear evidence the extraordinary disorders of contraction of which the diseased heart is capable. But for all ordinary purposes of diagnosis the finger-tips of the physician will hardly be helped by an instrument as difficult to manage [illegible] tracings is [illegible] ventricular wave R, with expiration and inspiration in the case of oblique leading off of the heart. This is in conformity with my first observations which showed how the lead off was more or less favourable according as the heart is more or less tilted, and with the demonstration given by Bouchard some years ago on the Roentgen screen of the fact that the heart is pulled down and rendered less oblique with each inspiratory descent of the diaphragm.

A few words of explanation are necessary to make clear the system adopted by Einthoven in the presentation of the positive and negative features of his electro-cardiograms. [illegible] ribed in giving [illegible] the left hand [illegible] of course, leads from the apex. He systematically takes three electro-cardiograms, the first with the right and left hands, the second with the right hand and left foot, and the third with the left hand and left foot; in all three cases the first-named extremity is base and the second-named extremity is apex, and the connexion with the galvanometer is always made such that negativity of base shall read upwards and negativity of apex downwards.

I think that the principal service hitherto rendered by this beautiful instrument has been to confirm and harden our acceptance of the doctrine that the contraction of the heart is essentially a wave of activity sweeping along a muscular tube from its venous to its arterial end.

From Figs. 1 and 2 the almost exact identity between the sequences of events in the heart of the dog and in that of man is clearly apparent; in both cases the electrogram is composed of an auricular element P and of a double ventricular element R and T; the most probable interpretation of these three positive waves is that they signify negativity of the auricle P, followed by an initial negativity R of the base of the ventricular mass at the commencement of systole and by a terminal negativity T of the base at the end of systole. This double negativity, which was pointed out many years ago by Bayliss and Starling and Gotch, can be understood by reference to the development of the ventricle as a twisted muscular chamber of which the auricular and aortic orifices are closely juxtaposed towards the base of the organ, so that a wave of muscular action sweeping over the whole mass begins at the base and ends at the base. This is very clearly the case in the frog's heart, where the ventricular contraction can actually be seen to terminate by contraction of the bulbus arteriosus, and where, mechanically as well as electrically, the contraction of the base begins earlier and ceases later than that of the apex. Thus in the frog's heart, as in he human heart, the base of the organ is twice in unbalanced negativity, the two phases B B being separated by a brief systolic interval during which the action of the base is balanced by the simultaneous action of the apex, so that the normal sequence of action as regards the ventricular mass is B A B. Figs. 3 and 4 illustrate this probable interpretation, and bring out very clearly by an example the essential identity between the ventricular contraction of a frog's heart and that of a man's heart, in complement to Figs. 1 and 2, by which the essential identity between the cardiac event in man and in the dog is made evident. In both cases shown in these figures each ventricular contraction exhibits two prominent elevations (base twice negative) separated by a depression (apex negative). These elevations correspond with Einthoven's waves R and T (Figs. 1 and 2). In the description that I gave in my "Introduction to Human Physiology" (first edition, 1890, p. 389) the ventricular sequence is described as base-apex-base, or B-A-B, B and B corresponding with Einthoven's R and T—i.e., in Figs. 3 and 4 each elevation corresponds to B, A being the valley between.

It must be admitted, however, that this simple explanation of the double negativity of the ventricle is not all-sufficient, and that there are features such as the variability in direction of the ventricular wave R and T in pathological states that are more easily accounted for on the supposition that "His's bundle" radiating from the auricular septum to the inner surface of the ventricles is a special channel of communication between auricles and ventricles, and that through this channel the ventricular mass can be brought into action simultaneously at many points or unequally and irregularly at different points. Normally the ventricular mass contracts as a whole, the systolic state being initiated and terminated at the base, but abnormally it is possible that an atypical systole may take origin at the apex or at other points of the mass by the channel of His's bundle, which although chiefly muscular as to structure, is also in part nervous, and is separate from the general muscular mass of the ventricle, apparently playing the part of a special conductor of impulses from auricle to ventricle. This is the explanation invoked by Einthoven, and one that I am disposed to accept as necessary, partly on account of the atypical systole occasionally witnessed on human electrocardiograms, partly on account of the undoubted sequence occasionally witnessed on the excised mammalian heart—

viz., negativity first of the auricle, then of the ventricle apex, and finally of the ventricle base.

The view that His's bundle is one channel does not, to my mind, necessarily entail regarding it as the only channel to the exclusion of the main mass of the vascular tube. Pathological observations are apparently confirmatory of the view that His's bundle is, so to speak, an extra channel or by-pass supplementary of the principal channel through the muscular mass of the vascular tube, for, on the one hand, in cases of allorhythmia where His's bundle has been found degenerated the degeneration has been found to extend to other parts, while, on the other hand, cases have been reported of well-marked degeneration of His's bundle where the cardiac rhythm had been previously observed to be normal.

In conclusion, it should be observed that the use of Einthoven's galvanometer is by no means confined to the investigation of the human heart, although no doubt this has hitherto constituted its most noteworthy application. The instrument, although its principle was previously utilised by Ewing and by Duddell, is practically a new departure in the hands of Einthoven as regards sensitiveness and precision and convenience. Essentially it consists of a silvered quartz fibre 15 centimetres long, weighing only 1/1000th milligramme, having therefore no appreciable lag or inertia and responding to a current as small as the millionth of a millionth of an ampère—i.e., far more sensitive even than the most sensitive mirror-galvanometers in ordinary use and superior in quickness to the most rapidly reacting capillary electrometer. In its less sensitive and handier forms Einthoven's galvanometer is by far the most efficient and convenient instrument for physiological purposes and is certain to displace sooner or later all forms of galvanometers and electrometers that are at present employed in the physiological laboratory.

THE CAUSE OF DEATH AFTER OPERATION IN ACUTE APPENDICITIS.

BY CHARLES A. MORTON, F.R.C.S. ENG.,
PROFESSOR OF SURGERY IN UNIVERSITY COLLEGE, BRISTOL; SENIOR SURGEON TO THE GENERAL HOSPITAL, AND THE CHILDREN'S HOSPITAL, BRISTOL.

AFTER operations for acute suppurative appendicitis some patients die with symptoms of profound toxic poisoning. The symptoms of an acute appendicitis are marked, but the child does not appear to be in a dangerous condition; an operation is performed, some focus of suppuration or a gangrenous appendix is found, pus is evacuated, and perhaps the appendix is removed. There seems good reason to expect recovery, and yet perhaps a few hours after the patient has regained consciousness, or it may be 12 or more hours later, the pulse begins to fail; there may be frequent vomiting (starting after the anæsthetic vomiting has ceased if it has been present), great restlessness, or drowsiness, or delirium, or coma, or jaundice, sometimes one of these symptoms, sometimes another, often several. The temperature rarely rises or, at any rate if it does, rarely exceeds what was present before operation, and more often does not reach above 99° F. There are no symptoms suggesting a spread of the abdominal mischief, nor is such spread found at the post-mortem examination. Abdominal pain, rigidity, and tenderness are markedly absent. These patients are not desperately bad at the time of the operation or immediately after it—i.e., they do not suffer from shock, and yet after an interval in which they seem to be progressing favourably these serious symptoms arise, and they do so, in my experience, almost always in children and not in adults. What are these symptoms due to, and what is their relation to the operation? These are the questions which I propose to consider.

It may be that the fatal result in some of the cases is in no way connected with the operation; for instance, in those dying three days later. They might have died in this way, at almost the same time, or even earlier, had no operation been performed, and no doubt few, if any, of them would have recovered without an operation, yet several of them died so soon after operation, whereas they were not *desperately* bad before, that one is driven to the conclusion that in some way or other the operation did hasten their end.

Excluding cases of diffuse peritonitis in which suppuration was extending widely in the lower abdomen, and cases of general peritonitis, and also those of mechanical obstruction from adhesions, and kinking in acute appendicitis, I have had 147 cases of operation in acute appendicitis—non-suppurative, suppurative, or gangrenous, and in these 147 there have been (up to a few months ago when this paper was written) 18 deaths. Ten of the deaths were of the nature I am considering in this paper, and two more cases referred to in this paper were deaths in diffuse peritonitis. It may be interesting to mention the other causes of death in the 147 acute cases. In two, rupture of the abscess occurred into the peritoneal cavity though external drainage was established; in two, acute bronchitis proved fatal; two patients died from prolonged suppuration; and one from general and one from portal pyæmia. There are only two cases in which the operation was followed by a spread of peritonitis; in one of these it was no more than would lead to protective adhesions in the neighbourhood of the drainage-tube, and in the other very little more and not enough to be the cause of death.

In some of the cases I am specially considering in this paper the symptoms are like those now recognised as due to late chloroform poisoning. Indeed, it is quite possible that the administration of chloroform has really brought on [illegible] in a patient rendered specially susc[illegible] [illegible]nous action of the chloroform by the action of a septic toxin on the tissues of the body. The septic toxin may so damage the tissues that the chloroform has a poisonous action it would not otherwise have. The fact that nearly every one of my cases has been a child is s [illegible] use, for it is well recognis [illegible] is much more common in [illegible] Harold J. Stiles[1] holds the view that the fatal result in many septic abdominal cases is brought about by the toxic action of chloroform in addition to septic poisoning. In cases of late chloroform poisoning fatty infiltration of the liver is nearly always marked, and we usually find acetone in the urine or the breath, and diacetic acid in the urine also. Some of my earlier cases of death with symptoms of toxic poisoning occurred before the condition of late chloroform poisoning was recognised, but in one of the more recent cases I failed to find any naked-eye appearances of fatty infiltration of the liver (Case 2 in abstract of cases) and in another microscopic section showed it to be very slight (Case 3 in abstract of cases). Acetone was present in the urine of the case in which there was no fatty infiltration of the liver. But if fatty infiltration of the liver is present it does not prove that the condition is due to late chloroform poisoning, for such a condition (though usually less marked than in delayed chloroform poisoning) is present in septic diseases, and acetone and diacetic acid may be present in the urine in so many different morbid conditions, or even in apparent health.

But we must also consider whether the symptoms could have been due to the absorption of a septic toxin, present before operation, but not absorbed until a raw surface was produced by the operation wound. The symptoms in all the cases could not have been produced in this way, for in one (Case 2 in abstract of cases), although the appendix was gangrenous, it was wrapped up in omentum, and there was no surrounding infection, and the whole of the septic focus was removed, leaving no pus-producing area to infect the wound; yet the girl died comatose in less than 24 hours. In another case (Case 7) there [illegible] at the time of remo[illegible] area infected from [illegible] gauze. In all the other cases there was the possibility of absorption of toxin through the recent wound, but if the symptoms were due to this, and this alone, such absorption ought to set in within a short time of the operation in all cases; for we know that it is before protective granulations form in a wound that it is best able to absorb poisonous fluids It might be that such symptoms would not start immediately after the production of the raw area, even if produced in this way, for the dose absorbed might for a short time be insufficient, and the lethal effect only produced after the absorption of some amount of the toxin in the course of several hours. But in Case 4 the symptoms did not come on for 24 hours after operation; in Case 9 not for 36 hours after, and in Cases 5 and 10 not for three days after. These intervals between the time of production of the raw surface and the time of the onset of symptoms seem to me too long to be consistent with the view that the two were cause and effect. It hardly seems likely that within three days, or even within 24 hours, enough toxin would not have been absorbed to produce symptoms when the toxæmia, when once established, was so great that death rapidly occurred, if the symptoms were entirely due to such absorption from the raw surface.

We must also consider whether in sponging out the pus in some of these cases I could have damaged the peritoneum, and led to absorption of toxin in this way. There was never any attempt to rub the peritoneum, only very gentle sponging, and this I do not think could have so injured it as to allow of toxin absorption to a greater extent than existed before. Moreover, the same objection would apply to this explanation as to that of absorption from the wound—the long interval before the onset of symptoms in some cases. Neither do I think destruction of peritoneal surface by the entrance of any antiseptic into the suppurating area can have led to increased toxin absorption. Several of the cases [illegible] were wrung out of no stronger lotion than 1 in 4000 biniodide of mercury, and wrung dry before being introduced into the peritoneal cavity.

Then the question must be considered as to whether any of these deaths were due to delayed or "secondary" shock. Only in one case was any marked failure of pulse present at the end of the operation—i.e., one could not say they suffered from shock at that time. This so-called "secondary shock" is a curious condition. Why should it occur? Is it really pure shock? Is it not more often sepsis with toxic absorption? The nature of certain of the cases could hardly be explained by such a thing. Frequent vomiting, jaundice, delirium, and coma are not symptoms of shock, primary or s[illegible]s were due t[illegible] was iodoform [illegible] drainage-tube, and in no other way was iodoform applied to the raw surface in the other cases.

It seems to me that when we come to ask ourselves what is the immediate cause of death in many cases, we can only give a most imperfect answer to our question. In very widely diffused or general purulent peritonitis we are not surprised if the patient dies, and we say that death is due to a toxæmia. But what is the nature of the poison, and does it act on the cardiac muscle or the nervous system? If on the nervous system, in what way does it produce death? Is it vaso-motor paralysis, as many believe it is in shock, or in what other way does it kill? Although the cause of death after severe injuries and operation (i.e., shock) has been so carefully considered and so fully discussed, yet the actual cause of death in many diseases has been very little investigated and about it very little is known. If a person has obstruction in the air passages and rapidly dies the mechanism of death is easy to understand; but why does a patient slowly fail and die because a malignant growth in his body has attained a very large size, or because there is inflammation of the membranes of his brain? And, as I suggested before, even if death in such diseases as septic peritonitis, spreading infective gangrene, and erysipelas is due to the absorption of some toxin due to the growth of micro-organisms, we know so little of the way in which it brings about the death of the patient that whenever a profound toxæmia is established, and we cannot drain away, or by stimulating excretion eliminate the toxin, its action is beyond our control. I do not forget the use of antistreptococcic serum, but I do not think many of us are able to place much reliance on its beneficial action. Moreover, it is more useful at an early stage of septic disease, for it is antibacterial rather than antitoxic in its action.

[illegible] me that though as yet the cause of these symptoms is doubtful, it might be wise to give ether by the open method to children suffering in this way. A general anæsthetic might be dispensed with altogether and spinal anæsthesia used in adults, but those cases which resemble late chloroform poisoning occur much more frequently in children, and children do not seem to me good subjects for spinal anæsthesia because they are so apt to get frightened and might not be very quiet. Moreover, in young children it would be difficult to say what would be the right dose to employ. Enough ether might, however, be given to produce anæsthesia for the lumbar puncture.

Can we prevent absorption of toxins from the raw surface of the wound? If facts supported the view that the symptoms are due to this, we might take strong measures to destroy its absorbing surface by applying a solution of chloride of zinc or pure carbolic acid, and packing between the drainage-tube and the raw surface with iodoform gauze. Even though absorption from the raw surface is quite a doubtful cause, it might be well, especially in children, whilst stitching up the wound to apply a little pure carbolic acid to the raw surface around the drainage-tube and to pack some strong iodoform gauze around the drainage tube so as to separate it from the raw surfaces. It might also be a wise precaution to employ Cathcart's suction drainage apparatus until the wound was granulating so as to drain the pus right away from the wound, or if the peritoneal cavity is well shut off from the abscess and frequent, or even might be employed to wash out in a very dilute form all *toxins*.

I have so far been writing of cases of death after operation in well-localised appendicitis or appendix abscess. But we must recognise the fact that in some cases of diffuse peritonitis the patients die rapidly after operation not from continued spread of the peritonitis but with simply a rapid and failing pulse and without vomiting, abdominal pain, or increasing distension (Case 11), and at the post-mortem examination there is very little extension of the peritonitis as revealed at the operation, and the actual cause of death is a question for consideration in the same way as in cases of localised appendicitis. I know how insidious the symptoms may be in some cases of spreading suppurative peritonitis, only a failing pulse and perhaps increasing distension, but in these cases I am writing about the post-mortem examination showed, as I say, hardly any increase of the peritonitis from the time of the operation.

ABSTRACT OF CASES.

CASE 1.—A boy, aged 12 years, was admitted to the General Hospital, Bristol, on Jan. 1st, 1908, with a very large appendix abscess which was opened and drained under chloroform. His condition was not very bad before operation. The temperature was 101° F. The pulse began to fail about 12 hours after operation, vomiting of dark fluid set in and con- [illegible] the next day his pulse could hardly be counted. [illegible] fusion was resorted to and several pints were [illegible] died within 48 hours of the operation without cerebral symptoms. At the post-mortem examination no spread of infection was found to have occurred within the abdomen. The abscess sac had not been packed with iodoform gauze, as it was well shut off from the peritoneal cavity at the time of the operation, but a very small piece had been used to pack the opening through the abdominal wall around the drainage-tube, as the tissues were sloughy and there was a little persistent oozing.

CASE 2.—A girl, aged 12 years, was admitted into the Children's Hospital, Bristol, on Feb. 11th, 1908, with a gangrenous appendix and a history of repeated rigors. There was a temperature of 103·8° F. on that morning, but she did not seem desperately bad and had a good pulse. I removed the appendix under chloroform; it was wrapped up in omentum and there was no surrounding infection. Unless portal pyæmia had already started I expected a good recovery. The pulse kept all right for several hours after the operation, but within 12 hours of the operation the patient became comatose with failing pulse and died. The temperature was raised, but not above 102°. Some acetone was found in the urine passed just after the operation. Vomiting was present, but this may have been ordinary anæsthetic vomiting. The liver presented no naked-eye appearance of fatty change. A little greenish-grey adherent clot was found in the portal vein, but no signs of embolic infection in the liver.

CASE 3.—A boy, aged six years, was admitted into the General Hospital under my care on May 19th, 1908, with diffuse purulent peritonitis in the lower abdomen and right loin from perforation of the appendix, which was removed. His pulse at the end of the operation was 140, but fairly strong. The operation was performed at 6 P.M. under chloroform. The patient had a very restless night, but vomiting was not frequent, and the pulse remained about 120 up to 8 A.M. On that morning the patient became unconscious with some retraction of the head and occasional rigidity of the arms, and he died in the afternoon. There was vomiting of dark fluid but not frequent vomiting. The temperature did not exceed 100·4°. There was no smell of acetone in the breath. The urine could not be obtained for examination during life, and a specimen removed from the bladder after death was unfortunately thrown away. The post-mortem examination showed very little, if any, extension of the peritonitis. The upper abdomen was free [illegible] trace of lymph on the spleen. There was [illegible] the base of the right lung. The pathologist [illegible] liver showed degeneration of liver cells in the centre of the lobules but very slight increase of fatty tissue, and that neither heart muscle, pancreas, or kidneys showed any degeneration on microscopic section.

CASE 4.—On August 23rd, 1907, I went into the country and operated on a boy, aged 12 years, with a large but well-localised appendix abscess, under chloroform. The pulse was only 100 and quite strong at the end of the operation. The patient seemed to be progressing satisfactorily when I saw him again next day, but that evening he became delirious, [illegible] night; he then became comatose and die[illegible]y. There was occasional retching. There [illegible] in the breath. The urine could not be obtained for examination. There was no jaundice. The highest temperature after operation was 101° F. No post-mortem examination was possible. Iodoform gauze packing was not used in this case; only a drainage-tube was inserted.

CASE 5.—A boy, aged 12 years, was admitted to the General Hospital on March 2nd, 1907, with a localised appendix abscess; operation was proceeded with on March 3rd under chloroform. Iodoform gauze packing was left in for three days, and when removed it still smelt strongly of iodoform. The patient went on well until the 6th (when the packing was removed) and then he began to get restless and vomiting set in. The pulse was 120. The highest temperature after the operation was 99·4° F., except a few hours after the operation when it was 100°, and at the time of death it was 101°. On the 7th the condition of restlessness continued and the pulse was 140. Jaundice was then also present and the vomiting had become frequent, the vomited matter being of a dark-brown colour. These symptoms continued until death took place on the 10th. The abdomen remained [illegible] the [illegible]-mortem examination we found that there ha[illegible] of a dry peritonitis up to the edge of the liver and somewhat over the stomach, but this seemed hardly enough to give rise to the symp[illegible] toxic poison from the [illegible] there had been no sig[illegible] only some moderate distension was present. No mechanical obstruction was found in the bile-ducts.

CASE 6.—A boy, aged ten years, was operated upon in the Children's Hospital on Dec. 5th, 1898, for localised appendix abscess under chloroform. A drainage-tube was inserted wit[illegible] The condition of the patient was goo[illegible] Vomiting of black material began 12 ho[illegible] not very frequent. The pulse began to [illegible] the end the patient became uncons[illegible] screamed loudly. He died 40 hours afte[illegible] ture remained at about 100° F. after the operation. The post-mortem [illegible]ritoneum, only some [illegible] the abscess had been [illegible]

[illegible]s, was operated on in the General Hos- [illegible] partly gangrenous appendix was removed [illegible] no suppuration outside the appendix. A very little iodoform gauze packing was left in and a drainage-tube. The patient's condition was good at the end of the operation. The gauze was removed two days after the operation. Up to that time there had been no symptoms since the operation, but soon after the removal of the gauze the patient became restless, two hours later [illegible] he became comatose and died. [illegible] f temperature until just before [illegible] only showed local suppuration [illegible]

CASE 8.—A boy, aged seven years, was admitted into the General Hospital in October, 1902, [illegible]ndix was removed and the abscess [illegible]rried out at 7 P.M. and the patient's [illegible] He was rather restless but otherw[illegible] surgeon at 11.30 P.M., and a very small hypodermic injection of morphine was given. I could not ascertain what the condition had been during the night but he died at 8 A.M. The post-mortem examination showed no spread of peritonitis from the original focus.

CASE 9.—A girl, aged 14 years, was admitted to the General Hospital on Dec. 11th, 1903, with a large appendix abscess. The appendix was removed and the abscess was drained. The patient was in a satisfactory condition [illegible] next day. [illegible] which was [illegible] lessness and a very rapid pulse (without a temperature above [illegible]) set in at 2 A.M. on the second night and the patient died on the following evening without further symptoms. The post-mortem examination showed no extension of infection within the abdomen.

CASE 10.—A woman, aged 30 years, was admitted to the General Hospital with a ruptured appendix abscess, and pus was sponged out of the pelvis and right loin. The patient went on satisfactorily until the third day after the operation, when she became jaundiced. Later she became comatose, and she died on the fifth day with a temperature of 105° F. The post-mortem examination showed some lymph on a few pelvic coils. This was noticed to be starting at the time of the operation, and it had increased afterwards, but was certainly not enough to cause death. There was no suppuration in the liver.

CASE 11.—A boy, aged ten years, admitted to the General Hospital on Feb. 10th, 1906, with diffuse peritonitis from appendix disease, was operated upon by sponging out the pus, removing the appendix, and draining. The patient died in 24 hours with a gradually failing pulse from the time of operation, but there was almost no vomiting, and no signs of increasing peritonitis were met with. There was very little, if any, extension of t[illegible] the post-mortem examination from what was [illegible]

CASE 12.—A boy, aged fi[illegible] to the Children's Hospital on Dec. 18th, 1902, with a large appendix abscess, resonant with the gas of decomposition, which was drained. On the next day the patient had a very rapid pulse, vomiting was present, and the abdomen was tender, and I foun[illegible] had set in. Death took place 36 hours after [illegible] of the [illegible]e iliac general peritoneal cavity was found. [illegible] muscle in the floor of the abscess sac. The highest temperature after the operation was 101° F.

Types of cases.—Not very bad at the time of operation or just after (with the exception of Case 11, in which the pulse was very feeble after the operation), though acute illness was present. Little or no pyrexia after operation. No spread of disease, present at the operation, was found post mortem.

Symptoms.—1. Rapid failure of pulse and frequent vomiting (Cases 12 and 1). 2. *Rapid failure of pulse and coma* and perhaps delirium, and vomiting: Case 2 (anæsthetic vomiting); Case 3 (some vomiting), and Case 4 (some retching). 3. Great restlessness, failure of pulse, jaundice, and then coma (Case 7). 4. Great restlessness and rapid pulse, without vomiting or cerebral symptoms (Cases 8 and 9).

Cases with very slight spread of peritonitis after operation, and not enough in any case to cause death or to account for the symptoms.—*Symptoms.*—1. Jaundice, coma, and very high temperature at end of case (Case 10). 2. Frequent vomiting, delirium, and coma (Case 6). 3. Jaundice, frequent vomiting, slow failure of pulse with almost no pyrexia (Case 5). 4. Rapid failure of pulse, continued vomiting, and other symptoms (Case 11).

PS.—Since writing this paper Professor W. E. Dixon and Dr. Harvey have published a paper[2] on the treatment of acute toxæmia. That paper does not deal with the forms of toxæmia referred to in the present paper, and therefore does not give any assistance in considering the cause of death in these septic cases; but the authors show that the effect of the diphtheria toxin frequently causes death by paralysing the vaso-motor centre, and therefore that such patients die in the same way as they do in surgical shock; and that injection of saline solution into the circulation is useful in the one condition as it is in the other. Perhaps it may be found that some of the septic toxæmias cause death also by paralysis of the vaso-motor centre.

PROSTATIC CALCULI:

THREE CASES ILLUSTRATING A NEW METHOD FOR THEIR SUCCESSFUL REMOVAL BY THE COMBINED SUPRAPUBIC AND PERINEAL ROUTES.

By J. LYNN THOMAS, C.B., F.R.C.S. Eng.,
SURGEON TO THE CARDIFF INFIRMARY AND TO THE ROYAL HAMADRYAD HOSPITAL, CARDIFF.

AT the Sheffield meeting of the British Medical Association I described a simplified method of performing prostatectomy by the combined suprapubic and perineal routes, and contended that from a theoretical standpoint the combined method should be the operation of choice, and in support of my conclusions I recorded 12 consecutive and successful cases. I now desire to record my experience of three cases of prostatic calculi treated successfully on the same lines as were indicated in that paper[1]—viz., firstly, by suprapubic cystotomy, and followed by perineal opening made transvesically and large enough to admit the forefinger from the perineum.

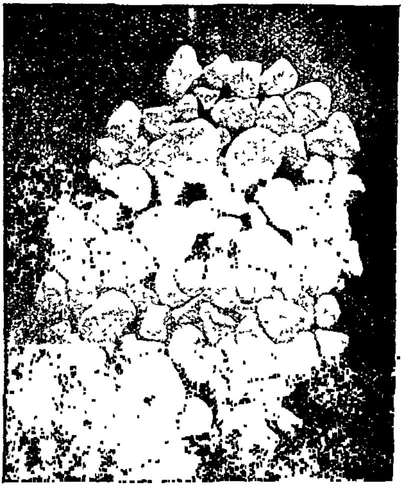
In my method of operating the patient is lying on his back with his thighs separated during the whole operation. I wish to draw special attention to the difference that exists between the perineal opening made in cases of prostatectomy and in those now under consideration; in the former the perineal opening does not involve the urethra at all, as it extends from *the bottom of the bed of the prostate*, whilst in the latter the opening is made through the membranous urethra. In the three cases which I now record I could demonstrate that the mucous membrane of the urethra was pushed down as far as the incised perineal skin before the point of the special prostatectomy forceps passed transvesically into the urethra, the well-known normal distensibility and strength of the posterior urethra allowing it to be readily done. My first case is a striking illustration that during the operation there is no serious disturbance of the anatomical conditions or relationship between the urethra and rectum, because in it there existed a recto-urethral fistula at the time of operation, which subsequently healed without giving further trouble. There need be no unnatural tension upon the parts between the rectum and the urethra if counter-pressure be applied to the perineum during the passage of the curved forceps through the bladder towards it. My present observations are confined to the treatment of these cases.

CASE 1. *101 prostatic calculi; recto-urethral fistula; stricture of vesical urethral opening.*—The patient, aged 63 years, had suffered for over 20 years from "stricture at the neck of the bladder" and had to carry with him, and use, catheters on and off owing to stoppage. For some months before operation he had been passing air bubbles through the urethra and quantities of slimy mucus with feculent odour and with acid urine. Per rectum the prostate felt enlarged and was exquisitely tender. A No. 6 catheter could with much difficulty be passed into the bladder. Dr. C. C. Shepherd and I had advised operation about four years before the patient submitted to it.

After performing suprapubic cystotomy the vesical urethral opening was found to be contracted, rigid, and unyielding to dilating force, so it was incised sufficiently to admit the tip of my forefinger which I then passed into a biggish pouch in the prostatic urethra bulging towards the rectum, and which was full of calculi represented in Fig. 1. Owing to the difficulty in removing the concretions and also on account of the highly septic condition of the cavity I passed my special forceps for prostatectomy to the bottom of the cavity and opened the perineum. By digital manipulation (the forefingers) I removed the 101 calculi through the bladder and the perineum. After thorough irrigation I fixed a five- [illegible] rubber tube into the bladder [illegible] ry was rapid and there were [illegible]e operation. Dr. Shepherd gave ether anæsthesia.

CASE 2.—The patient, aged 62 years, had suffered for about 12 years from irritability of the bladder, night micturition, and had had catheters used on and off for years. His trouble began when he was in South Africa. Mr. G. R. Sparrow of Cardiff, and Mr. T. J. Webster of Merthyr Tydvil were of opinion that he had enlarged prostate with chronic septic cystitis, but they were not allowed to pass a metal catheter.

FIG. 1.



On Jan. 23rd, 1908, I performed suprapubic cystotomy under ether anæsthesia, administered by Mr. Sparrow, and was assisted by Mr. Webster. After removing a large, soft, friable, vesical calculus (Fig. 2, marked "Vesical," weighing over one ounce when dry), the bladder and prostate seemed to be normal, and at my request Mr. Webster again examined per rectum and reported that the apparently enlarged prostate which had been previously diagnosed could still be felt. I therefore carefully inspected the base of the bladder and found a small opening about three-quarters of an inch behind the urethral orifice which led into a sacculus with a hard stone (Fig. 2, marked "Sacculus," weight half an ounce when dry) in it, situated between the prostate and rectum. This was removed by incising the opening into the prostatic urethra; and afterwards I again found eight small faceted calculi (Fig. 2, marked "Prostatic"). Perineal drainage was then established by pushing the special forceps through the urethra towards

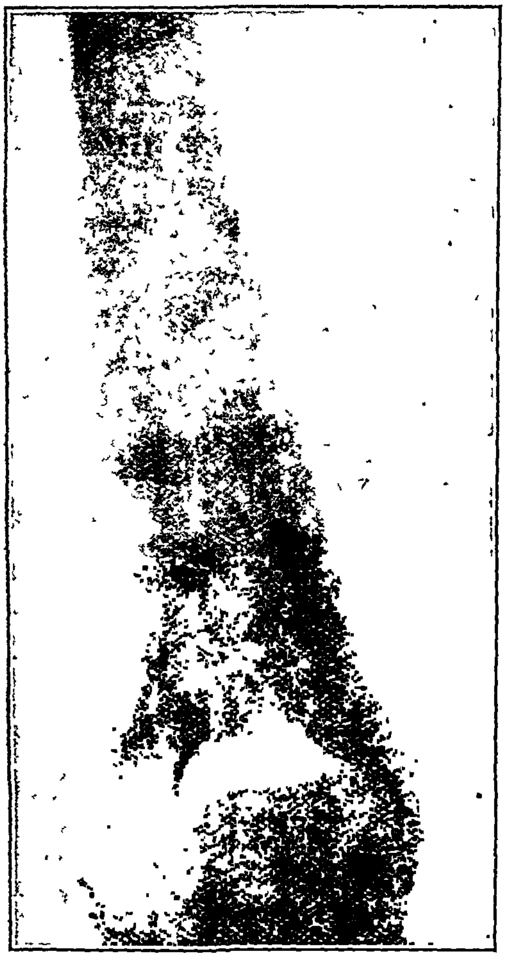
[1] For details see Brit. Med. Jour., Oct. 3rd, 1908.

with no suspicion of fluctuation or egg-shell crackling about it, the skin and muscles were not implicated, but the superficial veins were a little prominent and there was an enlarged gland in the right axilla. The arm was wasted and the muscles were weaker than those of the opposite side; the movements of the elbow-joint were unimpaired. Pain was only complained of when using the arm or on applying firm pressure. No other bone abnormality could be made out. There was no history of injury or of fracture, and the question of syphilis was carefully gone into, but no evidence of it could be obtained. The skiagrams showed marked changes in the structure and outline of the bone, and suggested to most of those who saw them the presence of a new growth.

FIG. 2.



Reproduction of skiagram taken on Feb. 1st, 1909, showing maintenance of improvement.

To exclude the possibility of a syphilitic origin mercury and potassium iodide in increasing doses were given for ten days, but as at the end of that time the swelling had increased both in measurement and as seen by skiagram, that treatment was abandoned, and the patient was advised to submit to an exploratory operation, to be followed if necessary by amputation; this, however, she refused to agree to, and, as an alternative, treatment by Coley's fluid was suggested and adopted.

We began with half-minim doses and increased them by quarter, half, and one minim until a maximum of nine minims was reached; the first injections were given into the arm outside the limits of the growth, but the later ones were injected into it, and 23 injections in all were given. They were followed by pain and swelling at seat of injection, with general malaise and headache, nausea and vomiting, and pains in the limbs and joints followed by the appearance of subcutaneous hæmorrhages resembling bruises, but with only slight rise of temperature and increase of pulse-rate. These after-effects were so unpleasant that we had some difficulty in persuading her to continue the treatment; she, however, submitted to it until August 13th, when the swelling had almost disappeared and the structure and outline of the bone had resumed its normal appearance.

A skiagram taken on Feb. 1st, 1909, shows that the improvement has been maintained.

Devonshire-street, W.

A NOTE ON NORMAL MENSTRUATION WITH ABSENCE OF THE BODY OF THE UTERUS.

BY ALEXANDER BROWN, M.B. LOND., M.R C S. ENG.

THE patient, who had been married for nearly three years, consulted me on account of sterility. She was most desirous of having a child. Bred in the country and of fine physique she had been perfectly regular in her periods from the age of 13 years. She was now 28 years old, about the same age as her husband, who was tall but not so strong-looking as herself. The periods lasted for four or five days and an experienced nurse testified to the normal loss. This nurse, who had known the patient from infancy, informed me that although she knew her to be an affectionate wife and very fond of children she was sexually cold and during childhood had pursued the sports of boys and had formed no girl acquaintanceships.

I examined the patient in bed, and bimanually could find no uterus and I failed to introduce a sound. On withdrawing my finger there was a little blood; the vaginal cervix appeared to be of normal size and shape but was congested, and the blood evidently came from the external os I advised a full examination under an anæsthetic. Accordingly a few days later I placed the patient under ether, and my friend Dr. A. Alexander conducted the examination, the result of which I afterwards confirmed. He found complete absence of the body of the uterus. On bimanual examination the state of the pelvic contents was striking; the examining finger and the outside hand clearly approximated with the vaginal cervix alone between them. There was absolutely nothing to be felt within the pelvis to represent the body of the uterus.

I am aware that a post-mortem examination could alone disclose the exact representation of the parts and that developmentally a uterus might then be demonstrated, but the case appears to be of considerable interest in that so gross a deficiency existed with normal monthly periods. No doubt the vaginal cervix supplied the monthly loss.

Bartholomew-road, N.W.

A FUTILE INQUEST.—An inquest reported in the *Western Gazette* of May 7th affords another proof that the coroner's law is in urgent need of reform. The jury were directed to inquire into the death of a woman, aged 28 years, who had died suddenly with symptoms of severe abdominal pain before the medical man who was summoned could reach the house at Thornford where she resided as housekeeper. No poisonous substance was found in the room. The witnesses who spoke as to the nature of the symptoms were unskilled, and no medical evidence was called nor was any necropsy made. The jury told the coroner that "Deceased appeared to have died from natural causes," and the coroner replied that "he had entered the statement that deceased was suddenly taken ill and suffered from severe pains, probably due to indigestion, which caused acute gastritis, and that she died in a natural way and not in an unlawful way." This elicited a protest from the foreman to the effect that "the jury said 'appeared' to have died," to which the coroner replied that "it was the same thing." Accepting the report as correct, the jury appears to us to have had a much sounder view of the nature of the evidence than the coroner. However the woman died, the coroner has taken a heavy responsibility in neglecting to prove his supposition as to the cause of her death in the only possible way—i.e., by ordering a post-mortem examination to be made. In the absence of any medical evidence the jury in effect very properly refused to bring in a verdict, and we trust it will afford a salutary lesson to the coroner in question on the futility of guess-work inquests.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

Exhibition of Cases.

A MEETING of this section was held on May 14th, Sir Thomas Barlow being in the chair.

Dr. Frederick Spicer showed a case of Paralysis of the Right Spinal Accessory Nerve. The patient was a man, aged 32 years, living in the Midlands, who had always enjoyed good health until the middle of January last, when he complained of sore-throat, weakness of voice, and pains on the right side of the head, right shoulder, and right arm. He was treated by his medical attendant until March 4th, but as he did not improve he was sent to London and was there found to have paralysis of the right vocal cord, the right side of the soft palate, the right sterno-mastoid, and the right trapezius. There was very considerable wasting of the muscles, with marked drooping of the right shoulder. He had had influenza some four months previously; there was no history of syphilis or injury.

Mr. Walter G. Spencer showed a case after reduction of an old Subcoracoid Dislocation of the Right Shoulder, complicated by fracture of the upper third of the humerus, by excavating the glenoid cavity through a posterior intermuscular incision. The patient was a man, aged 43 years, who was riding a motor cycle when a collision occurred; he was thrown violently and received severe injuries—viz., fracture of the base of the skull with concussion, fractured ribs, dislocation of the head of the right humerus, oblique fracture of the upper third of the shaft of the right humerus, and widespread ecchymoses about the right shoulder. While he was recovering from his head injuries the fracture of the humerus slowly united, with overlapping of the fragments to the extent of about two inches. As soon as he could he began to make every effort to move his shoulders and to use his arm, but after six months he had not made any progress; indeed, he thought that his arm was becoming more fixed to his side. The humerus was fixed to the scapula, which could be moved very little, and the oblique union of the humerus was not firm. Since the operation his arm could now be raised to the vertical without moving the scapula much more than normal. He could swing on a horizontal bar and use a 4 pounds dumb-bell. He had returned to work and each week had shown increasing ability to carry out overhand movements.

Dr. N. S. Finzi showed a case of Inoperable Recurrent Scirrhus of the Breast under Treatment by Radium. The patient, a woman, aged 78 years, noticed about eight years ago that the breast felt hard. About three years ago she had some pain and consulted her medical attendant, who removed the breast in April, 1906. About 12 months ago she noticed some hard lumps under the skin, and when seen at the Metropolitan Hospital by Mr. Peter L. Daniel in November, 1908, she had several masses of about the size of walnuts firmly bound down in the centre of the scar and the axilla, and a couple of nodules under the skin at the lower end of the scar. Under x ray treatment (four full doses to different parts of the scar) great improvement resulted and the subcutaneous nodules disappeared. The patient, however, did not attend for some weeks and the growth again became rapid and much larger than in November. She had two more doses of x rays on Feb. 24th and 28th of this year. From March 10th 5 centigrammes of radium, filtered through a silver tube 0·6 millimetre thickness and 1 millimetre thickness of india-rubber, were applied over the large mass for 53 hours, the position of the tube being altered once. On March 12th a dose of 41 hours was commenced in the axilla. The radium used was the pure bromide and was contained in a little glass tube within the silver tube. A considerable dermatitis developed in the two places, commencing almost at once and reaching a maximum in about three weeks. The area of this, however, was quite small and could be excised if required. By April 2nd the tumour had almost disappeared except for a little thickening between the two places where the application had been made. That proved to be a definite nodule, and a dose of 26 hours with filters of 0·6 millimetre silver and 1 millimetre lead, and six hours with 0·6 millimetre silver was given, starting on April 29th.

Dr. Finzi also showed a case of Epithelioma of the Lower Lip under Treatment by Radium. The patient, a man, was admitted to the Metropolitan Hospital in March last with a growth on the lower lip 4·5 by 2·5 centimetres in size. This had started as a pimple, which gradually became larger and became crusted over, and had been growing for 15 or 16 years. The rapidity of the growth had considerably increased for the last eight or ten months. There were enlarged glands under the jaw on both sides, but larger on the left than the right. Five centigrammes of radium bromide filtered through 0·6 millimetre silver were applied to the growth for 15 hours from March 1st, and the same quantity filtered through 0·5 millimetres of silver and four layers of lint for 28 hours from April 1st to the glands on the left side of the neck. Epilation was noticed on the neck about April 29th and on the left side of the upper lip on May 5th. Considerable improvement resulted both in the growth and the glands. Commencing on May 4th, another application of 22 hours was given to the lip, the filter this time being 0·6 millimetre silver and 0·5 millimetre lead and two layers of lint.—Mr. Rickman J. Godlee observed that in Paris radium was applied, not only by means of a small portion of the substance in a capsule, but also by spreading the radium into pads of different shapes and sizes.—Mr. W. G. Spencer mentioned a case of epithelioma of the tongue under treatment by radium at Paris for two months, with the result that the disease had spread to the glands of the neck.—Mr. C. Gordon Watson said that the latter of the two cases shown by Dr. Finzi was admitted under his (Mr. Watson's) care for treatment. The glands in the neck after the application of radium had not increased in size. Replying to Mr. A. E. J. Barker, Mr. Watson said that the growth was better in regard to surface and bulk and less in length and breadth.—Dr. A. Howard Pirie said that it was necessary to apply the radium in a capsule because it was apt to lose its power when spread out on a pad.—Mr. A. Pearce Gould pointed out the inadvisability of discussing any case still under treatment. He thought that there was but little evidence of actual healing over the growth.—Mr. E. H. Shaw said that microscopic examination did not show evidence of any actual healing at the edge of the growth. The radium treatment seemed to have assimilated the surrounding tissues in trying to overcome the growth.—Dr. Finzi said that in Paris nævi were treated with radium on pads. In Paris it was claimed that radium treatment was for precancerous conditions. As soon as the growth had infiltrated the tongue muscles it was past treatment.

Dr. Finzi showed a case of Arthritis successfully Treated by Iodine-lithium Ionisation.

Dr. Alexander Fleming demonstrated a simple method of Serum Diagnosis of Syphilis by the "Complement Deviation" Method. This differed from Wassermann's original method in the following respects: (1) an alcoholic extract of normal heart muscle was used instead of a saline extract of syphilitic liver; (2) the natural hæmolytic power of human serum for sheep's corpuscles was made use of, thus doing away with the necessity for the hæmolytic serum of a rabbit immunised against sheep's corpuscles and the guinea-pig's serum (complement); and (3) the amount of blood which could be collected in an ordinary blood capsule furnished an ample supply of serum for the test.

Mr. V. Warren Low showed a case of Pneumococcal Cystitis and Arthritis in a man successfully treated by a vaccine prepared from the patient's own organism. The conduct of the case by vaccine therapy was controlled by the estimation of the opsonic index.

Mr. Sidney A. Boyd exhibited a case showing Sprengel's Deformity of the Shoulder and Hirschsprung's Disease, with definite rectal obstruction.

Dr. F. Parkes Weber showed a woman three years after treatment by omentopexy and peritoneal drainage for Chronic Ascites connected with Hepatic Cirrhosis. The patient, aged 42 years, was admitted to the German Hospital on account of ascites in October, 1905. On Dec. 1st omentopexy was performed by Mr. F. Michels according to the method recommended by A. Narath[1] (a colleague and particularly in private practice. He emphasised the necessity of using the drug in a freshly prepared form.—Dr. HAULTAIN had used 1-200th of a grain of scopolamine with 1-6th of a grain of morphine during the first stage, when patients were often too ready to cry out for relief. Its effect lasted about from five to seven hours, and it had the advantage that during the second stage, if the pains were very severe, then a very small quantity of chloroform was required to relieve them. On several occasions he found the effects pass off and that when the second stage came on the patient exaggerated the suffering. In several cases the condition of the child gave very great anxiety when the dose mentioned above had been given, and he found it difficult to resuscitate the infant. If the child was born within two hours no results were evident, or after five hours when the effects had passed off, but it was between these times that he had met untoward results. He considered the drug of the very greatest value in helping suffering women.—Dr. ELSIE M. INGLIS had experience of its use in 43 cases, giving it in doses of 1-100th grain of scopolamine and 1-4th grain of morphine, repeated if necessary in three hours. It was useful in cases with a very prolonged first stage; these mostly ended with chloroform administration in the second stage, and she had also found that much less was then required. She had noticed rapid dilatation of the os under its influence.—Dr. J. HAIG FERGUSON had found it inconstant in its action, or this might have been due to idiosyncrasy of the patient. He used 1-100th grain of scopolamine and 1-6th grain of morphine, repeating the same dose of scopolamine if necessary without the morphine. As the patient was not so conscious of the pains then, these cases required more careful attendance of the medical man. One patient had expressed herself to the effect that she had some feeling of pain but in a far-away manner, as if the pains were in the other side of the room. He had found as much thirst from large as from smaller doses. It was useful in cardiac cases and where one had to hasten labour.—Sir HALLIDAY CROOM replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE.

Physical Deterioration.—The General Anæsthetics Bill.

A MEETING of this section was held on April 30th, Dr. W. R. DAWSON, the President, being in the chair.

Mr. J. B. STORY read a paper on Physical Deterioration. He said that there were no means of ascertaining with perfect certainty whether the population was physically degenerating or not. No statistics were available in the United Kingdom on this point. But it was known that urbanisation was increasing, and plenty of evidence existed to show that this tended to physical degeneracy. In support of this German statistics were quoted. Attention was called to the reports of three Parliamentary Commissions—(1) Interdepartmental on Physical Degeneration; (2) a Royal Commission, Physical Training, Scotland (1903); and (3) the recent Poor-law Commission. The first recommended a permanent anthropometric survey of all children and young persons, methodical physical instruction in all schools, and compulsory drill and physical exercises for all growing lads; the second made almost identical recommendations; and the third, in a majority report, stated that the most effective and thorough method of infusing into boys approaching adolescence a sense of discipline and self-restraint, both physical and moral, and of improving their physique for subsequent industrial occupations, would be a universal system of a short period of military training. Mr. Story commented upon the utter lack of any systematic physical education in Irish schools and made the following recommendations which were afterwards adopted by the meeting:—1. That a permanent anthropometric survey should be made of children and young persons. 2. That physical drill should be compulsory, in conjunction with a proper system of medical inspection, in all schools, primary and secondary. 3. That all boys between the ages of 14 and 18 who were physically fit should be compelled to belong to boys' brigades or cadet corps or to attend classes where physical drill of a military character was conducted. 4. That all youths at the age of 18 years (rich and poor) who were physically fit should be compelled to undergo a period of military training.—Dr. N. McI. FALKINER spoke from personal experience of the value attaching to boy scouting. Apart from the question of a territorial army military training would be in every way an advantage.—Professor E. J. MCWEENEY said he became convinced of the great utility of compulsory military training when living in Germany. The lack of coördination was very marked in this country and far too many of the children of the poorer classes were allowed to wander about the streets to acquire an anti-social character of mind and to feel themselves as outside the scheme of things. The German system impressed him with the feeling of solidarity.—Surgeon-General BOURKE spoke of his experience of military training. There was a great difference between squads that had only a few days' service and those that had longer periods. He could assure them that even three months made a decided improvement, and the Swedish system had been found to be of great advantage.—Dr. R. B. M'VITTIE thought that the teeth were, perhaps, the most important indication of degeneration. He could not see how a man was going to stand hard work if he had not good opposing molars. It had been shown that 86 per cent. of the children in schools in Great Britain had very bad teeth, and he thought the figure showed that the race was degenerating at a rapid pace. If there was to be more prolonged physical drill it should be under the control of the medical profession.—Mr. M. J. NOLAN spoke of the good results of the Swedish system in his asylum in Downpatrick.—The PRESIDENT said he had been converted to the doctrine of compulsory military service by a residence in Germany. The great advantage of early training was that it got a boy at the stage when he combined the self-indulgence of the child with some of the force of a man. It was a critical stage, and drill would be the salvation of the young men of the country.—Mr. STORY replied.

Dr. T. P. C. KIRKPATRICK read a paper dealing with the General Anæsthetics Bill now before Parliament, in the course of which he opposed the proposed exclusion of dentists from the ranks of the anæsthetists. In his opinion the course of instruction laid down for dental students of the Royal College of Surgeons in Ireland was quite sufficient to permit the dentists of the future to be entrusted, with perfect safety to the public, with the important duty of administering anæsthetics.—Dr. J. CRAIG said that Dr. Kirkpatrick stood almost alone in his defence of the dentists who were not also registered medical practitioners.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on May 7th, Dr. J. Walker Downie, the President, being in the chair.—Dr. W. R. Jack read notes of a case of Tuberculosis of the Bladder treated by Vaccine Therapy. The patient was a young woman, aged 32 years, a teacher by occupation. She had suffered from frequency of micturition with scalding pain for four years. The attacks came on acutely and passed off after varying intervals. In May, 1908, the urine was acid, of specific gravity 1020, and contained albumin and pus. Tubercle bacilli were readily detected in the sediment. On cystoscopic examination tuberculous ulceration was found in the trigone of the bladder and in the neighbourhood of both ureters. Dr. J. H. Nicoll removed the right kidney, the pelvis of which was found to contain a uric acid calculus coated with phosphates. Scattered tubercles were found through the cortex. The right ureter was swollen and gelatinous. Convalescence was uninterrupted. The attacks of pain recurred and in January, 1909, cystoscopic examination proved the ureteral orifices to be normal, but adjacent to the right orifice were one or two small white tubercles and two flat yellowish ulcerated surfaces, with rounded margins and evidently tuberculous. The patient's index to the tubercle bacillus was 0 68. On Jan. 22nd 0·0006 milligramme of Koch's bacillary emulsion was injected. A few hours of meatal and hypogastric pain followed. The index fell to 0·60, but rose steadily to 0·88 on the 24th and 1·08 on the 28th, and 1·10 on the 31st. The frequency of micturition greatly diminished and pain disappeared. On Feb. 2nd 0·0001 milligramme was injected. The index did not rise beyond 1·06. After the injection of 0·00012 on Feb. 14th the index fell to 0·81 and rose to 1·34. Some injections of a vaccine grown from a pure culture of bacillus coli found in the pus were also given and effected a marked diminution in the quantity of pus. Examination at this stage failed to discover tubercle bacilli in the urine and the symptoms steadily improved.—The President read notes of a case of Epithelioma of the Naso-pharynx treated by Radium. The symptoms were severe frontal headache and inability to breathe through the nose. Both nares were found filled with pus. The naso-pharynx was almost completely filled with a new growth, a piece of which was removed and was found to be a cellular epithelioma. Operation was refused and radium was tried. A small quantity of bromide of radium was passed into the naso-pharynx through the inferior meatus. It was at first left in for 15 minutes, but later was left in for an hour each day. After a week the patient could draw air through the nose and the headache was less severe. After six weeks of this treatment the tumour had entirely disappeared. He returned again, however, with symptoms of intracranial tumour, from which he died.—The President also reported three cases of Primary Epithelioma of the Uvula. Each tumour was removed with scissors, cutting away a considerable piece of the soft palate round the tumour. One case died ten years after from a malignant tumour in the right posterior triangle of the neck. There was no recurrence in the throat. The second case returned four years after with a scirrhous cancer of the left tonsil, with involvement of the cervical glands, which with the tonsil were removed.—Dr. A. A. Gray showed stereograms illustrating Normal and Pathological Conditions in the Middle and Inner Ear.—Dr J. Wyllie Nicol showed a New Form of Test-tube. The open end was inclined at an angle of about 45° to the length of the tube for the purpose of facilitating dropping in fluids, as strong nitric acid, from a bottle.

Reviews and Notices of Books.

Mendel's Principles of Heredity. By W. BATESON, M.A., F.R.S., Professor of Biology in the University of Cambridge. Cambridge: At the University Press. 1909. Pp. 396. Price 12*s.* net.

Professor Bateson's admirable book puts out in the clearest possible manner the whole story of Mendelism up to the present hour, and we say up to the present hour because work upon Mendelian lines, having for its object the making of the study of heredity into an organised branch of physiological science, is now being undertaken by so many capable experimenters in so many different fields of research that it is not necessary for Mendelism to mean the same thing, as far as detail is concerned, for more than an hour together. The principles, however, it must be assumed, will not vary, for if they do all the interesting work that is being done for the development of their application and in accordance with their promise would thus become meaningless or misleading.

Most of us now know the curious story of Gregor Mendel, the Abbot or Prälat of the Königskloster in Brünn, who read in 1865 to a local scientific society two papers upon plant hybridisation, the result of experiments carried on in the gardens of his institution, and there and then founded a school of research which had no scholars for 35 years, but which is now gaining adherents rapidly. Mendel's work was published in the Transactions of the Brünn Scientific Society, and in that form probably reached our Royal Society and Linnean Society, among other learned bodies. It attracted, however, no attention, which, as Professor Bateson shows in his biographical notes upon Mendel, was all the more extraordinary, because the researches and conclusions were germane to controversies and discussions which happened to be at that very time occupying the minds of several naturalists of the first rank. The work of the Prälat of Brünn, however, went unnoticed, to be rediscovered in 1900, some 16 years after his death as an unappreciated and disappointed man. In 1900 three papers appeared within a few weeks of each other giving the substance of Mendel's theory and experiments as displayed in his communications to the Brünn Society, and confirming the conclusions arrived at in certain directions from independent investigations. From that time forward, mainly owing to the enthusiasm of Professor Bateson, labour upon Mendelian lines has been undertaken with steadily increasing frequency, so that the fundamental question which medical men are asking—viz., Is there any practical value in the work to us?—must soon receive a definite answer, because the various scattered investigations will, or will not, group themselves into a scientific exposition of some of the laws of heredity, and success or failure can be tested with an approach to certainty. Many allow that the Mendelians have got so far already that they have placed the study of heredity upon a definite scientific basis as a branch of biology, and Professor Bateson brings forward a large amount of evidence to prove this; but whether he succeeds or no is for the time being of small importance. What is of importance is that these interesting researches should be pursued till a reasonable time has come at which we may ask the Mendelians for light and leading based upon their work. That time has not yet arrived. The work is in its infancy, or to be accurate it has just reached its teens, and it is too early to worry about its character or to take stock of its achievement It is unwise to assume too much for a youthful prodigy, and unfortunately it is easy to stunt or delay youthful growth by neglect. Let us do neither. We are not called upon to be credulous and we must pray to be delivered from an unreasoning scepticism; the right attitude is surely to resolve to give every chance to the new school of thought.

There is one thing that we are entirely tired of hearing and that is that the pursuit of Mendelian doctrines is a denial of the truth or value of the immortal work of Charles Darwin, and we agree with Professor Bateson's belief that if Mendel's work had come into the hands of Darwin the history of the development of evolutionary philosophy might have been very different, for it is certain that the presence would have been admitted of variations occurring as discontinuous phenomena. Many mighty Darwinian conceptions were so certainly true, so positively explanatory of much that had hitherto been puzzling, and so full of promise in many directions, that almost immediately after their publication special experiments in the science of genetics ceased to take place, or at any rate ceased to be carried on by many men of science. The scientific world agreed to accept in its entirety and without controversy the doctrines of pure selection, so that those who were engaged upon the examination of individual and discontinuous phenomena were made to feel that they were simply wasting their time. It is impossible to conceive an attitude of mind that would have been more positively distasteful to the great Darwin himself than to have all individual experimentation directed towards the support of any theory; but undoubtedly this is what occurred, and because of this comparatively little systematic work has been done in the study of genetics. Mendelism, therefore, when re-discovered in 1900 had a practically clear field, and Professor Bateson's book describes the progress that has been made, and the directions in which future effort is intended. "For a period," he says, "we shall perhaps do well to direct our search more especially to the immediate problems of genetic physiology, the laws of heredity, the nature of variation, the significance of sex and other manifestations of dimorphism, willing to postpone the application of the results to wider problems as a task more suited to a maturer stage. When the magnitude and definiteness of the advances already made in genetics come to be more generally known, it is to be anticipated that workers in various departments of biology will realise that here at last is common ground. As we now know, the conceptions on which both the systematists and the speculative biologists have based their methods need complete revision in the light of the new facts, and till the possibilities of genetic research are more fully explored the task of reconstruction can hardly be begun. In that work of exploration all classes of naturalists will alike find interest. The methods are definite and exact, so we need not fear the alienation of those systematists to whom all theoretical inquiry is repulsive. They are also wide in their scope, and those who would turn from the details of classification as offering matter too trivial for their attention may engage in genetic inquiries with great confidence that every fragment of solid evidence thus discovered will quickly take its place in the development of a coördinated structure."

There is room, therefore, for many labourers in the vineyard. The descriptions given by Professor Bateson of the experimental work done by himself and Mr. R. C. Punnett with fowls, by Miss E. R. Saunders with certain flowers, by Miss F. M. Durham with canaries and mice, by Mr. L. W. Newman with moths, by Mr. C. C. Hurst, and many others, display the wide range over which observations are now being made, and furnish clear and interesting reading for those who have mastered, with the assistance of the first two chapters, the kind of way in which the Mendelian regards the origin of species. One section in Professor Bateson's book will certainly be read by medical men with close attention—i.e., the chapter upon the connexion between heredity and sex. In this chapter there are set out the reasons for believing that sex may be found to be a result of gametic differentiation. The evidence from breeding experiments and the part which sex plays in determining or limiting the descent of certain characters in heredity are considered, the thesis being that the facts as to the limitations which sex introduces into the descent of a varietal character are consistent with the possibility that sex itself is a Mendelian character. Now some Mendelian characters can be bred for with certainty, so that the next inference should be that the predetermination of sex can be arrived at. Professor Bateson wastes no time in dealing with the numberless theories which have been put forward to explain the causation of sex, nor does he dwell upon the enormous importance to the world that the possibility of deciding the sex of the offspring would be. He narrates the work done by the Mendelians, and in a brief summary dwells on the need of extended investigations.

We have read this book with the greatest possible interest and recommend it to all our readers.

The Causation of Sex: A New Theory of Sex based on Clinical Materials, together with Chapters on the Forecasting of the Sex of the Unborn Child, and on the Determination or Production of Sex at Will. By E. Rumley Dawson, L.R.C.P. Lond., M.R.C.S. Eng. With 21 illustrations. London: H. K. Lewis. 1909. Pp. 196. Price 6*s*. net.

The problems concerned with the causation of sex have been a theme of intense interest to medical writers from the earliest times, and the hypotheses which have been put forward by different authors are so numerous that it would be a matter of difficulty to enumerate them all—a task which we have no intention of essaying. Unfortunately, in many instances the attempts which have been made to solve the complex problems concerned have too often been carried out with an absence of that scientific precision which is essential if we are to arrive at the truth of this matter. It is futile to suppose that we shall ever make any progress in this inquiry except by the patient accumulation of data of proved scientific accuracy, but as a rule it has been attempted to make the facts ascertained fit in with some preconceived hypothesis.

An example of this kind is to be found in a new work on the causation of sex, by Mr. E. Rumley Dawson. In this book the author, with honest simplicity, entirely ignores and rejects the work that has been done upon animals other than man; denies that one spermatozoon alone can be concerned in fertilisation; throws aside as useless to his thesis all the researches that have been carried out with regard to the division of the chromosomes; and asserts that it is illogical to assume "that a chance single spermatozoon besides fertilising the ovum nucleus" can have anything to do with determining the sex of the child or the transmission of hereditary qualities. His theory is this: that the male parent has no influence in the causation of sex, and that male ova are restricted to, and come only from, the right ovary and female ova only from the left ovary. In support of this view, which, apart from the denial of any paternal influence, is only a resuscitation of one of much antiquity, the author has collected every conceivable fact, authenticated or unauthenticated, which can lend any support to his hypothesis. The objections are ignored or denied, and the explanation of such difficulties as the presence of both sexes in birds with one ovary is got rid of by the ingenuous explanation that what applies to fowls cannot apply to man. According to the author the right ovary is larger than the left, and therefore more boys are born than girls. Mr. Dawson further maintains that the action of the ovaries is an alternate one, and he believes that the right ovary ovulates one month and the left ovary the next month. Following on the view of the alternate ovulation of the ovaries, the author maintains that he can forecast the sex of the coming child. The researches of J. H. Teacher and T. H. Bryce upon early human ova and their proof that ovulation must occur at different periods of time during the month are left conveniently out of account.

It is sometimes mortifying to read the comments of scientific writers upon the value of so-called medical evidence, but when we read a work of this description we feel that they have some cause for their complaints. We could wish that Mr. Dawson had devoted some of the energy and time which he has expended on the production of this book to attaining an elementary knowledge of the laws of scientific evidence. What is wanted is, not theories based on insufficient data, but the patient, unwearying accumulation of large numbers of proved facts. When we have these as a basis on which to build, then, and then only, shall we be in a position to attempt to solve this absorbing problem.

Recent Advances in Organic Chemistry. By A. W. Stewart, D.Sc. With an Introduction by J. Norman Collie, LL.D., F.R.S. London: Longmans, Green, and Co. 1908. Pp. 296. Price 7*s*. 6*d*. net.

It is a pleasure to take up a text-book on organic chemistry which is not written in the wilfully orthodox method that presents at its best a mere collection of facts of which, as Professor Norman Collie says, often neither the explanation is vouchsafed nor the connexion with one another traced. Such a method is mainly responsible for having reduced organic chemistry in the minds of many to "a vast rubbish heap of puzzling and bewildering compounds. ...... The game of permutations and combinations goes on, the chief object apparently being merely to supplement the already existing myriads of laboratory-made organic compounds." The criticism is a just one when applied to even standard text-books, and the result is that the reader's memory is overtaxed and his faculty of originality and criticism remains unstirred. In Dr. Stewart's book we find summed up the present position of the researches which have been carried out in organic chemistry within the last ten years, and it must be admitted that this period has been a fruitful one. He has dealt with the subject not historically but from the synthetic point of view, each step in the synthesis being awarded a separate section, "so that at any moment the reader can see exactly how far he has advanced, and can easily refer back to any stage which he may wish to read again." This is the author's excellent plan of treatment which sharply differentiates his book from all those text-books to which we have alluded. The chapters speak in the clearest possible terms of the wonderful constructive work which chemists have achieved, and present the ingenious lines of reasoning which have resulted in this success. Among medical readers, perhaps, the chapter on the synthetic alkaloids will attract most attention, although of equal interest to medical science is the chapter on the polypeptides, a branch of research which promises some day to culminate in the building up of that important class of compounds the proteins. We note that in this section the author departs from the nomenclature recommended by a committee of the Chemical and Physiological Society in regard to protein substances. He refers, for example, to albumenous bodies and albumens. At one time the word "albumen" signified the white of egg, but it was agreed to drop the word altogether and to substitute as a general term "albumin" preceded by the word indicating its origin, and so albumen became egg-albumin, the albuminous substance of blood serum-albumin, and so forth.

The book is instructive in regard to past work and is calculated also to stimulate fruitful thought and action in the future. It is thus something more than a text-book, for it points the way to fields yet untilled in regard both to practical and theoretical considerations.

Movable Kidney: A Cause of Insanity, Headache, Neurasthenia, Insomnia, Mental Failure, and Other Disorders of the Nervous System; a Cause also of Dilatation of the Stomach. By C. W. SUCKLING, M.D. Lond., M.R.C.P. Lond., Consulting Physician to the Queen's Hospital, Birmingham, &c. 1909. Birmingham: Cornish Brothers, Limited. *Pp.* 155. *Price* 5*s.* net.

THIS is the second edition, although this fact is not stated on the title-page. Some three years ago we reviewed the first edition, and our opinions then expressed have undergone no change on the perusal of this issue. Those who examine the abdomen frequently know how very commonly a kidney may be found to be moveable and yet no symptoms are present that can be ascribed to this mobility; and in fact, this harmlessness of the condition is the rule. In such cases as these it is in the highest degree unwise to tell the patient that a moveable kidney is present, for if he or she be in the least degree neurotic the idea of possessing a moveable kidney will become an obsession and every ache and pain will be put down to it; many new aches and pains will also arise in response to the demand. That severe symptoms may result from a moveable kidney few will be disposed to deny, but it is easy to over-estimate the importance of the mobility, and this, we think, Dr. Suckling has done. Some of the cases reported in this book are certainly striking, and in some of them we are willing to agree that the operation of nephropexy was, in part at least, responsible for the improvement, but in most of them it is probable that the operation acted as a suggestion. We are told that the patient stays in bed for four weeks after the operation; this rest in itself should have a beneficial effect on many of the symptoms. However, we agree that cases do occur in which a moveable kidney is causing symptoms, and that fixation of the kidney will be very beneficial to the patient. But care should be exercised in the choice of cases, for it is easy to seize upon a common lesion like mobility of the kidney and account through it for various nervous conditions which may happen to be present.

Contributions to the Physiological Theory of Tuberculosis. By CHARLES CREIGHTON, M.D. Aberd., sometime Demonstrator of Anatomy, Cambridge Medical School. With 64 illustrations in the text. London: Williams and Norgate. 1908. Pp. 242.

AFTER studying the histogenesis of experimental tuberculosis in rodents and comparing it with the evolution of certain structures in the placenta of the same class of animal, Dr. Creighton reviews the whole subject of tuberculosis, including the "spontaneous" disease occurring in man and bovine animals. As a result of his own observations and of his interpretation of the results obtained by other workers he rejects the bacillary theory of the causation of the disease, and endeavours to establish in its stead a physiological theory, according to which the genesis of tubercles and the occurrence of secondary and necrotic changes in connexion with the lesions so induced are not specific, but own a physiological analogue in the histological processes occurring in the placenta. It is difficult to state Dr. Creighton's theory succinctly, or even to quote his own statements regarding it, since his style is discursive and he refrains from summarising his contentions into an actual definition or outline. The nearest approach to it is on page 134, where he gives what he refers to as the "point of view" from which he approaches the pathogenesis of bovine and human tuberculosis in the following words. "Nearly the whole of bovine tubercle is a chronic disorder of nutrition, to which breeding may predispose in a very high degree. A large part of human tubercle is also chronic and a disorder of nutrition to which also breeding predisposes greatly." Further, on page 135, after the statement that "No experiments on the smaller mammals can ever reproduce the manifold circumstances of human and bovine tubercle," he explains the results obtained in experiments by saying, "Means are used which in effect, if not in intention, produce a rapid dissolution of the blood extravasations, disintegration of the blood discs at innumerable centres and corresponding tissue reactions due to the efforts which the organism will always make (in non-lethal conditions) to meet an emergency or crisis, howsoever arising." In order to study the evidence upon where these somewhat cryptic generalisations are based it will be best to review briefly the material presented by the writer.

The book is divided into three parts, the first of which is devoted to the histogenesis of experimental tubercle. After summarising previous researches upon this subject, Dr. Creighton considers the special features of the tuberculous lesions in the animals most often chosen for laboratory studies of the disease—viz., rabbits and guinea-pigs—and then records his own observations on the histogenesis of tuberculous lesions in the lung of the rabbit and in other organs of rodents. In regard to the lung, after injection of emulsified bacilli into the vein of the ear the first condition which results is widespread microscopic thrombosis followed by diapedesis into the air cells and a dispersion of the nuclear chromatin of the leucocytes. These nuclear particles cling to red blood corpuscles, which they serve to build up into the large mononuclear protoplasmic (epithelioid) cells of rodent tubercle. Later a branched plasmodium appears in the thrombosed vessels, apparently due to fusion of these epithelioid cells. Such a blocked vein forms the centre of the actual tubercles, the bulk of which consists of a protoplasmic tissue, trabecular, syncytial, or plasmodial, with large nuclei usually vesicular and clear. The changes are summed up as "blood dissolution and plasmodial reconstruction." The second part is devoted to the placental analogies of these processes, and an attempt is made to establish the formation in the placenta of the plasmodial or syncytial tissue which it contains from the substance of red corpuscles extravasated from the maternal vessels. The necrotic, caseous, and hyaline changes which occur in the placental structures and are eventually the cause of its separation after its work is done are regarded as further supporting the analogy. The histological changes in the two forms of caseation are described as identical, and Dr. Creighton therefore refuses to regard the caseation of tubercle as a remote action of the bacillus. The third part deals with human and bovine tuberculosis. The histological characters of the various lesions produced in tuberculosis of different organs are analysed in the light of the views previously expressed. The giant cells are regarded as thrombi or blocks in the vessels, while the epithelioid cells are said to be formed from leucocytes and certain cells of the ground substance through the assimilation of the extravasated red blood corpuscles.

It will be seen that Dr. Creighton's views are startlingly heterodox. For him the bacillus is not specific in its effects—its primary action, and its only direct action, according to his view, is upon the red blood corpuscles, and similar results may be produced by other agencies. He scornfully rejects the doctrines of immunity and scoffs at the "metaphysical jargon" in which they are "couched." At the same time he brings no rebutting evidence, but simply ignores the subjects of bacterial toxins, of agglutination, and of the reaction to tuberculin, all of which rest upon definite experimental evidence which cannot be brushed aside by mere ridicule. His histological studies are of interest and are obviously worthy of careful consideration, but we cannot regard his contention of the non-specific character of tubercle as proved. That the histological changes own a physiological prototype is surely no sufficient reason for denying to the tubercle bacillus a specific activity in the genesis of tuberculosis, since on his own showing that organism can, and does, inaugurate the changes which eventually lead to the production of tubercles. In place of the definite conception of a specific infection Dr. Creighton offers only a vague and indefinite speculation as to a disorder of nutrition, and he fails to make clear what actual part the bacilli play in the production of the "spontaneous" disease.

Intestinal Auto-intoxication. By A. Combe, M.D., Professor of Clinical Pediatry at the University of Lausanne (Switzerland), &c. Together with an Appendix on the Lactic Ferments, with particular reference to their Application in Intestinal Therapeutics. By Albert Fournier, formerly Demonstrator at the Sorbonne, Paris. Only authorised English adaptation by William Gaynor States, M.D., Clinical Assistant, Rectal and Intestinal Disease, New York Polyclinic, &c. London: Rebman, Limited. 1908. Pp. 461. Price 16*s.* 6*d.* net.

Considerable attention has been paid in recent years to the subject of the bacteriology of the alimentary canal and of the affections due to the chemical changes which result from microbial action. The book before us sets forth Professor Combe's personal experiences in this field and at the same time refers to a great number of researches by other observers. He starts by defining the term auto-intoxication, and excludes from it toxæmias in which the poisons are formed outside the body and even those formed within the body under the influence of microbes introduced incidentally from without. Intestinal intoxications are, however, included as being due to perverted action of bacteria normally present, and apparently in the author's view symbiotic, in so far as they normally take part in the process of digestion. He limits his study in the present volume to intoxications arising from faulty proteid metabolism. Microbial action in the intestine is found to resemble pancreatic digestion or the action of strong alkalies on proteins. Absorption of poisonous bodies from the gut is facilitated by inflammation of its mucous membrane. Defence against absorbed poisons is carried on partly by the cells of this layer of the intestine, partly by the liver, and partly by certain glands, such as the thyroid, pituitary, and suprarenal bodies. When abnormal putrefaction has occurred in the gut it may be lessened by diminishing the amount of proteins taken, by introducing antagonistic bacteria, by intestinal antiseptic drugs, and by purgatives and lavage of the gut.

The book contains much that is worthy of study by those who are interested in a branch of medical study that is still in a very rudimentary stage. The translation leaves a good deal to be desired. Some sentences are scarcely intelligible, and the punctuation is extraordinary. "Dose" and "dosage" are not used in English for "estimation" of quantities of substances not employed as medicines. We are accustomed to the habit of medical writers of writing compound words (e.g., heart-disease) without hyphens, but to print terms such as "muco entero colitis," "meningeo spinal," "lacto bacilline" thus as separate words is carrying the licence of ignorance rather far. The translator seems uncertain even as to the spelling of certain words; thus we find "cariokinesis," "kariolysis," and "karyolysis." Mis-spellings which we are prepared to regard as misprints are also unduly common—"salycilate," "practiced," and so forth; and we know of no authority for the use of "ileus" for the ileum or lower part of the small intestine.

School Hygiene. By Robert A. Lyster, M.D., Ch.B., D.P.H., B.Sc. Birm., B.Sc. Lond., County Medical Officer of Health for Hampshire, and Chief Medical Officer to the Education Committee of the Hampshire County Council, &c. Second edition. London: W. B. Clive, University Tutorial Press, Limited. 1908. Pp. 388. Price 3*s.* 6*d.*

The publication of a second edition of Dr. Lyster's book on School Hygiene has afforded him an opportunity of adding a chapter on the organisation of medical inspection in schools. In this chapter he gives some useful suggestions in regard to the work of the medical officers for schools, and also as to the methods of recording and analysing the results obtained by the examination of children. He defines as the essential object of routine medical examination to discover the children who are abnormal, and to point out to the parents the necessity for seeking medical treatment. He rightly deprecates the giving of diagnoses to the parents as likely to lead to friction with those in actual medical charge of the child. In our review of the first edition we commended this text-book as a useful one for those concerned with the education of the young, and it is only necessary to state that in so far as this edition is concerned any alterations made are in the nature of improvements.

Worthing Hospital. — Corresponding with the growth of the town of Worthing have been the increased demands upon the Worthing Hospital. During the year 1898 there were 1818 out-patients and 227 minor accidents; during 1908 the figures respectively were 2732 and 468. The honorary medical staff in the past has numbered four, but with a view of lightening the duties, the governors, in considering the question of the vacancy caused by the death of Mr. A. H. Collet, decided on May 14th to increase the medical staff from four to seven, one of the new members of the staff to be the anæsthetist to the hospital. The rules of the hospital were so altered as to admit of the increase in the staff, and a new rule was also passed requiring that every medical officer shall retire on attaining the age of 65.

FROM
THE LANCET LABORATORY.

SPHAGNOL PREPARATIONS.

(PEAT PRODUCTS (SPHAGNOL), LIMITED, 18 AND 19, QUEENHITHE, UPPER THAMES STREET, LONDON, E.C.)

ATTENTION may be directed to the claims of sphagnol preparations in regard to their use in the treatment of eczema and other skin troubles, since there appears to be little doubt that sphagnol is effective owing to the fact that its active principles consist, amongst other things, of the antiseptic substance creasote combined with sulphur. Sphagnol derives its name from the fact that it is a distillation of peat, and the oil appears to have a value similar to ichthyol in skin diseases, such as acne, herpes, rosacea, and eczema. Sphagnol has the advantage of being non-corrosive and non-irritating. According to some printed statements upon the subject sphagnol in the form of soap and ointment appears to act very effectually compared with other applications used in skin diseases. The soap, we find, is very pleasant to use, and is evidently prepared from desirable materials. It lathers well and imparts a feeling of softness to the skin. Besides a medical soap containing 50 per cent. of sphagnol there are prepared also a toilet and nursery soap containing 5 per cent. of sphagnol, a shaving soap with the same amount, and an ointment containing 10 per cent. of this interesting peat product. Lastly, it is reported that suppositories containing 10 per cent. of sphagnol have been employed with success in the treatment of hæmorrhoids.

P. G. B. BRANDY.

(WILSON AND VALDESPINO, LIMITED, 5, NEW LONDON-STREET, LONDON, E.C.)

We can take no objection to the statement that this is a pure grape brandy 14 years old. Its mellowness on the palate bears evidence of its maturity, while the results of analysis reveal the presence and amount of secondary constituents commonly found in a matured pot-still grape spirit. It has quite a distinguished flavour and of the kind that is appreciated by connoisseurs of genuine old brandy. The secondary constituents amounted to the following in parts per 100,000 parts of absolute alcohol present: aldehydes, 40·00; furfural, 1·50; ethers, as ethyl acetate, 185·00; and higher alcohols, 140·00.

SANATOGEN.

(THE SANATOGEN CO., 12, CHENIES STREET, LONDON, W.C.)

This interesting compound of milk protein and phosphorus in organic combination has recently been improved in regard to its flavour in compliance with the peevish propensities of children and the sick. Certainly the flavour of sanatogen as it is now prepared leaves little to be desired and thus successfully meets an objection which has to be reckoned with. There is abundant evidence of the value of sanatogen as a restorative and food, and more particularly in cases of general debility.

LACTITIA.

(THOMAS CHRISTY AND CO., 4, 10, AND 12, OLD SWAN LANE, UPPER THAMES STREET, LONDON, E.C.)

We understand that this infant food preparation made from buttermilk is identical with a similar preparation in Holland called Nutricia. Its chief merit appears to be that it is made from buttermilk, which, though not showing a composition replete in all classes of food, and especially of fat, is well known to be very digestible. In Nutricia the deficiency of fat is made up by the addition of a special preparation of wheat flour. The whole is of a pasty consistence containing, according to our analysis, 66·46 per cent. of water. The protein amounted to 10·48 per cent., the fat to 2·44 per cent., the milk sugar to 10·00 per cent., the starch to 9·34 per cent., and the mineral matter to 1·28 per cent. It is debateable whether the fat in milk finds an efficient substitute in a carbohydrate, but evidence is given of the success of this food for infant requirements. Possibly the use of buttermilk gives it special digestive quality, and the modified carbohydrate may serve in the same way as barley water in preventing formation of indigestible lumps during gastric digestion.

LACTEOL TABLETS.

(AGENTS: ROBERTS AND CO., 76, NEW BOND STREET, LONDON, W.)

The activity of these tablets as regards their lactic acid producing power was proved by their effect upon fresh milk. The acidity of the milk was doubled in two hours and quadrupled in 24 hours. They therefore may be trusted for the antiseptic treatment of the intestinal tract as in auto-intoxication and in catarrhal conditions.

SOYA FLOUR.

(THE HULL OIL MANUFACTURING COMPANY, LIMITED, STONE FERRY, HULL.)

We have examined a sample of edible soya flour from the above firm and the following are the results of our analysis: moisture, 8·90 per cent.; protein, 55·50 per cent.; starch carbohydrate, 29·00 per cent.; and mineral matter, 6·60 per cent. No less than 38 per cent. of the preparation proved to be soluble in water and a large proportion of the soluble substances consisted of protein. There can be little doubt, therefore, of its nutritive and digestible character, while the flour should be valuable for those patients for whom an excess of carbohydrate is undesirable.

INVALID PORT (MARTINEZ).

(VICTORIA WINE CO., 12-20, OSBORN-STREET, LONDON, E.)

This is supplied by well-known shippers in the Alto Douro and may be described as a robust invigorating port suitable for invalid purposes where, under medical advice, the use of such wine is sanctioned. According to our analysis the wine contains 21·19 per cent. of alcohol by volume; extractive matters, 9·63 per cent.; mineral matter, 0·13 per cent.; and sugar, 9·00 per cent. The volatile acidity was a negligible quantity, amounting to merely 0·06 per cent. The port may be described, therefore, as non-acid. The flavour is "round" and fruity.

GLUCAPHEN.

(FRANK A. ROGERS, 327, OXFORD STREET, LONDON, W.)

Glucaphen is described as a compound containing the proteid ingredients of milk and wheat combined with suitable small doses of glycerophosphates. The results of our analysis confirmed this description, the following figures being obtained: moisture, 10·30 per cent.; protein, 77·61 per cent.; fat, 6·39 per cent.; and mineral matter, 5·70 per cent. The mineral matter consisted practically entirely of phosphates, partly of mineral origin, but which are largely due to the glycerophosphates present. Not quite 50 per cent. of glucaphen proved to be soluble in cold water, so that the statement in regard to its digestibility may be accepted. The food has already received practical testimony as to its nourishing value, and more particularly in the case of patients debilitated by disease or those possessing feeble digestive power.

IMPERIAL DOUBLE STOUT.

(THE NEW CROSS BREWERY, POMEROY-STREET, LONDON, S.E.)

This proved to be a well-brewed malt liquor containing a notable amount of malt extractives. Analysis showed these extractives to amount to 6·45 per cent., while the mineral matter, chiefly phosphates, amounted to 0·35 per cent. As far as we can find, there is no point about this stout calling for further special remark.

THE LANCET.

LONDON: SATURDAY, MAY 22, 1909.

The Oration before the Medical Society of London.

THE annual oration of the Medical Society of London, delivered by a physician or surgeon of recognised eminence in the profession, usually affords material for comment or criticism. Dr. H. D. ROLLESTON, the orator of this year, whose wide experience and comprehensive knowledge of medical literature render him peculiarly fitted for the honour, chose two separate though cognate subjects for discussion—viz., the classification and nomenclature of diseases, and appended an interesting but too brief reference to diseases due to treatment. With so wide a range of controversial matter to deal with Dr. ROLLESTON is critical and analytical rather than constructive in his remarks, and being of logical mind indicates the limitations and defects of our present systems of classification and nomenclature, while he refrains from propounding new ones, though he occasionally forecasts the probable directions in which progress will be made.

In sciences such as botany and zoology, in which the present state of knowledge is sufficiently advanced to permit of the application of a system, classification and nomenclature go hand in hand, but even here changes not infrequently have to be made as the result of research, as witness the frequent changes of name of some of the causal agents of diseases such as the ankylostoma duodenale and the treponema pallidum. Dr. ROLLESTON gives an interesting history of some of the more important systems of classification of diseases since that of FELIX PLATER in 1680, and refers in feeling terms to their fruitless character and their forgotten graves in the dust of libraries. He mentions especially the systems of CULLEN and JOHN MASON GOOD, both of which were for a time employed by Dr. WILLIAM FARR at the General Register Office but found to be unworkable. Little interest has of late been taken in nosological problems in this country, except in regard to the official nomenclature of diseases which follows no special system and is convenient rather than scientific. One of the most recent attempts at classification is that of LANCEREAUX and PAULESCO in France in 1907, which, after modification by a commission of the *Académie de Médecine*, was favourably reported on. For the most part these systems fall into two groups: first, symptomatic and regional; and secondly, etiological. There are obvious defects and difficulties about both of these, since the former would group together conditions upon superficial resemblances, while the latter would sometimes be inconvenient from a descriptive point of view—e.g., to quote an illustration given by Dr. ROLLESTON, peritonitis is more conveniently classified as an abdominal disease than as a local manifestation of infection with various organisms; moreover, classification in cases of mixed infection would be difficult on a purely etiological basis. He is therefore of opinion that a compromise of the etiological and regional systems is, for the present, *faute de mieux*, to be preferred to a rigid adherence to either. An interesting distinction is made between a disease and a symptom-complex or group of symptoms, the former owning a definite and special cause, the latter being a group common to several different causes. Dr. ROLLESTON points out that as our knowledge advances conditions formerly regarded as individual diseases are proved to be only symptom-groups, and, on the other hand, that some conditions now regarded as individual diseases are in reality group diseases, a group disease being defined as "a characteristic collection of symptoms which may be due to any one of a group of allied organisms." Of such group diseases, enteric fever and influenza are instanced as examples.

On the general text of classification Dr. ROLLESTON makes some interesting observations on the future of the physician and on the relations of physicians and surgeons. The former broad classification of diseases into medical and surgical has practically become obsolete since surgery and bacteriology have so extensively and so successfully invaded the domain of medicine both in regard to diagnosis and treatment. In the future the outlook for the pure physician, as Dr. ROLLESTON at once humorously and pathetically expresses it, "between the surgeon and the deep sea of bacteriology," is a parlous one. He thinks that the only remedy is to accept the inevitable trend towards specialism, and so to rearrange the existing spheres of influence that one man treats at least one group of diseases from start to finish, as is already the case in regard to gynæcology and laryngology. He therefore suggests that to this end "the general physician and general surgeon should be merged and should reappear as medical officers to departments or wards for special study of the body." Such medical officers should be trained to perform the operations which may be required in connexion with the region of the body of which they make a special study. The difficulties which would be encountered in establishing such a radical change in the professional scheme of this country would no doubt be considerable, and Dr. ROLLESTON discusses some of them. The first objection, that physicians being unskilled in operative technique would only be slowly replaced by their specially trained successors, could be met by the appointment of special operative assistants during the period of transition. The arrangement and allotment of the various regions and their diseases to specialists would also at first possibly lead to difficulties, and Dr. ROLLESTON briefly outlines a general grouping. But his suggestions that there might well be a department for fevers and for conditions of doubtful diagnosis, and that the out-patient departments would probably have to be less specialised so as to ensure a general education both for the medical officer and for students, indicate one of the greatest difficulties in connexion with such a system—viz., the method of selection of the cases to be sent to the special departments. Another obstacle to such a rearrangement would be the reluctance of the surgeons, who would not relish giving up some of the more lucrative part of their work. Yet another difficulty is the educational aspect of the change, for while no doubt the student would receive excellent teaching in the special departments from those in charge of them, yet it is necessary that he should be instructed in the general principles of the diagnosis and treatment of disease, since training by specialists only is likely to lead to too narrow a view, and to hide the fact that disease is an abnormal condition of the patient and not an entity. Dr. ROLLESTON admits that his suggestions may seem visionary, but points out that the principle is already in practice in the case of gynæcology and obstetrics. It is possible that eventually some such re-arrangement will come about, indeed it, or something very like it, is already an established condition in some countries, but with our innate conservatism it is probable that in these islands the change will be a gradual one, unless the principle of operation by physicians becomes accepted, when the existing specialties would soon become self-contained. The system has much to commend it, for it must be confessed that it would be more rational that, when called in to make a diagnosis, the physician should be so trained as to be able to carry out the treatment which he suggests. The patient applies to the medical practitioner for treatment, and it is small wonder that he sometimes finds it difficult to appreciate a scheme which requires more than one person to afford him the relief he needs.

If classification is in an unsatisfactory condition nomenclature is in a worse, and here Dr. ROLLESTON is critical but without making much suggestion for improvement. He is one of the few authorities who have a kind word to say for the application to a disease of the name of its discoverer, even for compound names, such as the Stokes-Adams disease. We do not share his views, but we allow that apart from doing honour to and keeping known the names of masters in medicine this system of nomenclature is non-committal as to the nature of the disease. On the other hand, controversy as to priority may lead to multiple synonyms, as in the case of exophthalmic goitre, which has, as Dr. ROLLESTON mentions, no less than seven observers' names attached to it. He discusses the different forms of nomenclature and regards the pathological method as the most satisfactory, but this is not applicable in diseases of which the morbid changes are not yet known. In other instances the popular or folk names of diseases are so firmly established that it would be difficult to replace them. A standard nomenclature is highly desirable, not only for statistical purposes so as to enable figures from different sources to be compared, but also to get rid of the multiplicity of synonyms, which are confusing and unnecessary. The official nomenclature of the Royal College of Physicians of London was first undertaken in 1857 and published in 1869. It is now subject to decennial revision, the last edition having been published in 1906. It is the standard by which the medical profession in this country is more or less guided, but perhaps as pathological knowledge advances an international system of nomenclature comparable to that established in anatomy may be achieved.

The concluding section of Dr. ROLLESTON'S oration is highly interesting, and deals with the subject of diseases and morbid conditions due to treatment. Owing to limitations of time he was only able to refer briefly to some of the more obvious of these, but the subject is one which might usefully be considered in detail, and there is no one from whom we would rather hear the full story than Dr. ROLLESTON.

The Rôle of Anæmia in Anæsthesia.

MORBID conditions of the blood have been recognised of late years as constituting important factors in the prognosis of surgical operations. Both from the point of view of the surgeon and from that of the anæsthetist graver risks are run by patients whose blood has suffered depreciation through disease or hæmorrhage than is the case with patients whose blood count is normal and whose hæmoglobin standard is satisfactory. In a paper contributed to the *Intercolonial Medical Journal of Australasia* of Jan. 20th Dr. R. T. SUTHERLAND reopens this subject, dealing with anæmia and the incidence of fatality under chloroform among the anæmic. He has analysed 900 recorded cases of chloroform administration at the Women's Hospital, Melbourne. The blood pressure was measured in these cases and of course was found to be lowered, as always obtains during the use of chloroform. In young women the blood pressure averaged 110 to 130 mm. Hg, and those with a high pressure, we are told, did not do well under chloroform. Among the women aged 45 years and above the average blood pressure was 100, and no untoward symptoms occurred under chloroform. The blood was examined also, and it was found that the incidence of danger under chloroform fell most upon patients who were anæmic and in proportion to the degree of anæmia. Other conditions—age, sepsis, blood pressure—appeared to be dominated by the blood state. Anæmia from whatever cause acted prejudicially when chloroform was employed.

These conclusions are noteworthy. Dr. SUTHERLAND regards anæmia as causing danger under chloroform owing to (1) the fact that in anæmia, while the total volume of blood is increased, the relative number of corpuscles is decreased; (2) the larger volume of blood allows more chloroform to be absorbed; and (3) the poor quality of the blood leads to malnutrition of the heart and so renders it more liable to chloroform poisoning. Dr. SUTHERLAND has been led to employ ether for anæmic subjects and has met with satisfactory results. The second contention advanced is probably unsound, at all events in its entirety, as the recent work done on the action of chloroform has revealed the fact that the red cells are the active carriers of chloroform as of other anæsthetics, and so it is doubtful whether the blood of anæmic subjects does absorb more chloroform than is the case with normal individuals. The contention that the tissues are ill nourished is no doubt the main factor in producing danger in such persons, and this applies with even greater force to the tissues of the central nervous system than to the fibres of the myocardium. MCWILLIAM and others have proved that in the case of certain of the lower animals acute dilatation of the heart occurs when chloroform is inhaled, and there appears to be little doubt that when the musculature of the heart is poorly nourished this dilatation is accentuated and is liable to pass beyond the degree which is consistent with ultimate contraction. This fact probably explains the tendency to heart failure under chloroform to which Dr. SUTHERLAND draws attention. It is, however, the nervous system which suffers most in anæmic states. Dr. LEONARD HILL'S work has taught us that the central nervous system when depleted of blood or supplied with blood of poor quality is peculiarly liable to be affected by drugs. A dose of chloroform, which is well within the safe limit if supplied to a normally nourished medulla, will destroy the nerve cells the vitality of which is lowered by starvation. It is matter of common clinical experience that anæmic persons, more especially those in whom the bloodlessness is the result of chronic morbid processes, frequently take anæsthetics badly and are liable both to circulatory depression of more or less severity and to storms of irregular nervous action often making for respiratory failure or inadequacy. The rôle which poverty of hæmoglobin plays is probably that it leads to chronic oxygen starvation—a condition consistent only with depressed tissue vitality. That chloroform reacts more dangerously than ether is explicable when it is remembered that the former is a powerful protoplasmic poison; the latter seldom destroys cells unless used in enormous quantities—quantities which are outside the range of the usages of the anæsthetist. And this consideration probably gives the key to the problem presented when chloroform has to be used for patients suffering from advanced anæmia. It is not the chloroform which kills so much as the use of large quantities for prolonged periods and a concomitant deprivation of oxygen. The actual quantity of chloroform required for anæmic patients is far less than in the case of healthy subjects, and when oxygen is employed *pari passu* with the anæsthetic one of the chief dangers is diminished almost to the vanishing point.

The effect of oxygen in protecting tissues from chloroform toxæmia has been demonstrated experimentally by Professor C. S. SHERRINGTON and Miss SOWTON and clinical experience supplies ample corroborative evidence. Methods which do not enable the anæsthetist to estimate the results of his dosage except by the advent of dangerous symptoms must be always perilous for patients who are anæmic. This is so because restriction of the quantity given is the only chance of safeguarding them from initial dangers, and also because their tissues once subjected to overdosage are so readily destroyed that resuscitative measures are seldom of any avail. Dr. SUTHERLAND has done a useful service in commenting upon this aspect of anæmia, since, although many surgical writers have insisted upon the dangers of general anæsthetics for persons in whom the blood count has revealed a marked depreciation of the corpuscular constituents, they have failed to realise that the danger lies, not so much in the anæsthetic, as in the manner in which it is employed. The inquiry is really far-reaching and involves not only the question of how far chloroform when introduced in massive doses destroys the red corpuscles—that it does so is certain—but also how far it is capable of destroying the active glandular tissue of organs such as the liver and the kidneys. In acidosis anæmia is a fairly constant factor, and malnutrition of tissue probably plays an important part in bringing about the necrobiosis of epithelium which is the prelude to abeyance of glandular function. It is sometimes said that anæmic persons "take anæsthetics well," and the statement may be accepted by the superficial observer, since the actual induction of anæsthesia is often simple in the case of the asthenic. However, there can be no doubt, when we recall the facts which experiment has demonstrated, that the dangers in these cases are of a nature which is not revealed in the gross phenomena incident to induction; they are insidious, far-reaching in their effects even when giving little warning of their presence until catastrophe occurs. Anæmia must be accepted as proof of a general tissue starvation and therefore of a greatly lessened power of resistance to drugs such as chloroform. To be forewarned is in such cases to be forearmed.

The Factors of Sex.

ALL medical men are perforce students of the phenomena of heredity, and the doctrines of Mendelism have consequently attracted the close attention of many of our readers. Medical men may not be prepared to endorse the claim that the application of Mendel's method of research has so clarified the study of heredity that this study has now become for the first time an organised branch of physiological science, but all must allow that abundant and suggestive results have accrued from the observation of a very wide range of zoological and botanical types. Among the latest developments of work along these lines is an attempt to show that the etiology as well as the influence of sex can be reconciled with Mendelian principles; and though it is a far cry from this position to that of ability, for example, to prophesy whether the infant on whom a crown or an estate should devolve will be male or female, any evidence that sex is determined by gametic differentiation will be welcomed by earnest students of heredity as a matter of enormous promise. Work in this direction will be upon practical and definite lines.[1] At present the essential factors which determine the sex of the fœtus are not known, but this want of accurate information has not in the least deterred many of those who have devoted their attention to the subject from supplying from the imagination that which was lacking in their knowledge. There have been put forward many theories to account for the sex of a child; some of these are over 2000 years old and some are of our own time, and the modern theories have been, some of them, as fanciful as the ancient. The conditions prevailing in the invertebrate animals are very different from those obtaining in the vertebrata, so that it is a little dangerous to maintain that the determining cause of sex in the lower animals is identical with that in the higher animals and in man. It is by no means proved that, in the respect of the determination of sex, mammals and the lower vertebrates are identical, or even that man resembles other mammals on this point, though it is extremely probable. These uncertainties have tinctured all deductions.

---

[1] See the review on p. 1461 of Mendel's Principles of Heredity, by Professor W. Bateson.

Inasmuch as a woman has two ovaries, it was suggested very early in the study of the subject that one ovary supplied male ova and the other female; a similar differentiation of function was ascribed to the testes, and the union of like with like was supposed to give rise to a fœtus of that sex, while if unlike met no fertilisation resulted. Such theories as these have for the most part been discarded, but in a modified form Mr. E. RUMLEY DAWSON[2] has recently revived the idea, maintaining that the right ovary of a woman contains only male ova and the left ovary has only female ova, while he considers that the father has no influence on the sex of the ovum. This differentiation between the functions of the two ovaries is usually considered to be answered by the case of the birds, in which the right ovary atrophies and only the left survives to supply all the ova of both sexes, but it is hardly safe to take for granted that the arrangements for the sexing of ova in the bird must be the same as those in the human being. Mr. DAWSON brought forward many arguments and facts in support of his opinion, but the verdict must be that his theory has no proper scientific foundation. Some ten years ago the theory put forward by Professor SCHENK received much attention; he held that if the urine of a woman contained any sugar whatever, even an amount so small as to be recognisable only by the phenyl-hydrazin test, there was a high probability that she would give birth to females rather than to males. In order that she might have male children Professor SCHENK advised that her diet should be so modified as to cause the total disappearance of the sugar. It may be taken for granted that the theory has broken down, for it was so easily to be tested that it has certainly been put to the trial, and if there had been any successes which could not be explained by coincidence we should certainly have heard much of them. The fault of most of the theories advanced hitherto is that there has been but little attempt to find facts, except to support some special theory. We know so little of the subject that the chief desideratum now is the collection of facts. Facts are needed on which to base a sound theory, and statistics, if rightly handled, should at least provide useful suggestions, but very few statistics are available.

It is known that in European races more boys than girls are born, and the average is almost constant—106 boys to 100 girls—and if regard be paid to stillbirths the excess of boys is still greater, for many more stillbirths occur with male children than with female. Nothing certain is known as to the reason of this disproportion, though some suggestions have been made. Another interesting fact is that amongst illegitimate children the excess of males is less marked than it is amongst legitimate children, the proportion being only about 103 boys to 100 girls. Little, however, has been done in the direction of obtaining statistics as to the variations in these proportions and their apparent causes, and therefore a paper recently read before the Royal Society by Mr. WALTER HEAPE is of special value. The title of the paper was "The Proportion of the Sexes Produced by Whites and Coloured Peoples in Cuba." It was based on the records of the Sanitary Department of Cuba, in which details are given of the births and stillbirths both of the white and coloured people of that island; and these records of births also distinguish between those which are legitimate and those which are illegitimate. The numbers are large and therefore of special value; they deal with the years 1904, 1905, and 1906, and during these three years there were in all 171,297 births and 6407 stillbirths. These totals are from monthly records for each of the three years and for each of the six provinces into which Cuba is divided. In each case the proportion of males for every 100 females has been calculated. The first noteworthy point that may be extracted from these statistics is that the white inhabitants produce a larger proportion of males than do the coloured people. For the whites the proportion varied from 106·8 to 110·5, with an average of 108·4. For the coloured population the proportion varied only from 101 to 101·2, with an average of 101·12, and this racial difference was shown both in the live births and in the stillbirths This marked racial difference is probably due to heredity, for the white inhabitants of Cuba mainly came from Spain. The sex ratio in legitimate and illegitimate births is given in figures relating to both white and coloured populations. In each of them the illegitimate births show an increase in the proportion of female children. In whites the total legitimate births are 107·76 males per 100 females, while the illegitimate are only 104·4 males per 100 females. In the coloured race the legitimate births are 106·76 and the illegitimate are only 96 76 males per 100 females. Mr. HEAPE points out that this difference cannot be a result of heredity, but must follow from some physiological conditions which modify the metabolic activity of the woman; he suggests that this exceptionally active metabolism in the mother affects favourably the development and ripening of female ova.

Another point of interest brought out by these statistics is that in Cuba there are each year two sharply defined breeding seasons, each of which corresponds to a change of temperature; one in the autumn occurs shortly after a sudden change from great heat to cooler weather, and the other in the early months of the year at the time when the cool weather of winter is giving place to spring. This effect of change of climate is seen also in the relative proportion of the sexes of the children produced, for at the breeding seasons when the increased metabolic activity of the mother is present there is a definite increase in the proportion of female births, and this is seen in both races. The effect of town as compared with country life on the sex ratio is also worthy of attention. The proportion of females born in the towns is considerably higher than in the country. No law of heredity yet known to us can account for this variation; it seems obviously due to extraneous forces, and of these perhaps food and climate are the chief. The statistics in short furnish evidence that in the human subject extraneous forces can exert a very definite influence on the proportion of the sexes. The matter is worthy of the fullest study. It would be well if the statistics of the British Isles could be more informative on some of these minor the human being, and that was in a case in which the cannula method had been previously employed unsuccessfully. The transfusion was very satisfactory; in fact, too much blood was given by the donor. The use of the lateral branch of the vein already mentioned is to enable the surgeon to see by taking off the clamp if any blood is flowing. The chief difficulty in all these methods of direct transfusion is found in determining how much blood is being transferred. Many cases have occurred in which the surgeon was under the impression that much blood had passed, but the fact that the blood pressures both of the donor and of the recipient were unaltered made it certain that none or very little blood had been transferred. An increase in the hæmoglobin of the recipient certainly shows a successful transfusion, but there is no close relation between the increase in colouring matter and the actual amount of blood received. The alterations in the blood pressures have also been used as a gauge, but there are many other factors which vitiate any accurate estimate being based on them. Weighing the donor and the recipient would be satisfactory, but the practical difficulties are almost insuperable. Even if the rate of flow from the artery be gauged previously to the anastomosis this rate could not be used with much value to estimate the quantity transfused. The dangers to the recipient are four: first, the possibility of a hæmolytic action of one blood on the other; secondly, the entrance of air or emboli into the vein; thirdly, the employment of a donor with a communicable blood disease; and fourthly, over-distension of an enfeebled right heart. The operation is without real danger to the donor, but it is well to take care not to abstract too much blood. During the operation continuous rectal infusion should be employed or a saline infusion may be administered at the end of the operation. We consider that the comparative simplicity of Dr. Hartwell's method is a strong argument in its favour, and in suitable cases where direct blood transfusion is indicated it is deserving of a trial. It has the great merit that no real suturing of the vessels is needed, and yet the blood in passing from the donor to the recipient does not come into contact with any structure likely to give rise to rapid clotting.

---

[2] See the review on p. 1462 of "The Causation of Sex," by Mr. Rumley Dawson.

A CRUSADE AGAINST FLIES.

NOW that it has been conclusively established that flies convey disease, let the nation wage war against these repulsive insects and take steps as far as possible to exclude them from among us. The campaign should be begun at once for the fly season is near at hand, and there can be little doubt that if everybody did his best to exterminate the fly a very distinct advantage to the public health would be gained and a most interesting example afforded of the lessons which progressive medicine teaches. It is not always possible to trace the origin of illness, but it is easy enough to give valid reasons why the fly can be the introductory agent. Purely medical aspects apart, the fly is not particularly scrupulous as to its environment: it alights at one time on most offensive material and at another it is on the food in the kitchen and at the table. One of the earliest experiments we remember to have seen showing the connexion of flies and disease was that in which a common blue-bottle was allowed to walk across a piece of freshly sliced potato. The potato subsequently developed colonies of micro-organisms all along the track taken by the fly, while elsewhere no development took place. The important question remains how best to get rid of the fly. Fly-papers and sticky strings are unsightly, and the struggles of a fly to release itself from a sticky substance is not an entertaining spectacle. In our own experience the best exterminating agent is a weak solution of weak formaldehyde in water (say two teaspoonfuls to the pint) and this experience has been confirmed by others. It would appear that flies are attracted by a weak solution of formaldehyde, which they drink. Some die in the water, others get as far only as the immediate vicinity of the plate of water, but all ultimately succumb, and where they occur in large numbers, hundreds may be swept up from the floor. It is consoling to know that by this method the flies have died under a dose of a fluid which is fatal to disease organisms, a fluid also which is inoffensive and for practical purposes non-poisonous. The method at once provides a means of diminishing the scourge, and of securing to some extent what is most desirable, the disinfection of the slain.

THE LYNN THOMAS AND SKYRME FUND.

IN another column we publish an abstract of the report of Mr. William Sheen, the honorary secretary of the Lynn Thomas and Skyrme Fund, upon the raising of the Fund, together with an account of the ceremonials to be observed at its presentation on June 4th at Cardiff. The eminent French surgeon, M. Lucas-Championnière, President of the International Society of Surgery, is to make the presentation and will also give an address upon the Modern Treatment of Fractures, which in the circumstances will have great topical interest. The presence of a foreigner and of one who is such a leader in his profession as M. Lucas-Championnière is one more proof of the truth of the saying that science knows no politics and is additional evidence of the friendship existing between ourselves and the French nation. We join our congratulations with those of our professional brethren at Cardiff to Mr. Lynn Thomas and Mr. Skyrme on the successful result of the appeal, not only in that its result has been of pecuniary service to them, but also because it shows that they have won the sympathy of their professional brothers.

HYDATID FREMITUS TRANSMITTED THROUGH THE THORAX AND FELT BY THE PATIENT.

AT a meeting of the Société Médicale des Hôpitaux of Paris on April 2nd M. A. Chauffard reported a case in which hydatid fremitus was observed under new conditions. The patient was a butcher, aged 33 years, who in his occupation was frequently brought into contact with hydatid disease. His thorax was asymmetrical; the lower part of the chest on the right side projected and the intercostal spaces were enlarged. The right chest measured 48 centimetres in circumference and the left 41. On percussion hepatic dulness extended as high as the nipple and downwards four fingers' breadth below the ribs. Radioscopy showed a dome projecting from the antero-superior part of the liver and extending as high as the nipple. The blood contained 3 per cent. of polynuclear eosinophiles. On placing the fingers of the left hand across the back of the right chest below the angle of the scapula, and lightly percussing in front over the fifth or sixth rib with the right index finger, a series of small undulatory vibrations (hydatid fremitus) was clearly perceived. This fremitus was also perceived by the patient, who compared it to the undulation produced by throwing a stone into water. Hydatid fremitus could not be obtained in the ordinary manner by percussion on one of the fingers placed on the anterior part of the thoracic projection. Thus the case presented two peculiarities: the hydatid fremitus was obtained only across the thorax, and it was clearly perceived by the patient himself. M. Chauffard suggests that the vibrations were both transmitted and perceived by the costal arches, and that the very delicate sensibility of bone to vibrations, for example to those of the tuning fork, which has been shown to exist by the researches of M. Egger, should be taken into account. This form of hydatid fremitus can be obtained only in similar cases to that now described—large cysts rising above the convexity of the liver. Fremitus in connexion with hydatid cysts is a useful sign when present, but is only found in a minority of the cases, since the conditions for its production are not always fulfilled. It would appear that the cyst must be of a certain size and that the tension of its walls must not be too great. Thus it is sometimes found that after partial aspiration a fremitus may be elicited over a cyst from which it was not previously obtainable. It was at one time supposed to be due to the impact of daughter cysts against one another, but it can certainly be obtained over cysts from which they are absent. A somewhat similar thrill can sometimes be obtained in other cystic swellings. In the above case the transmission of the fremitus across the chest, while it could not be obtained by percussion on the anterior surface, is of special interest. A similar sign has been described in effusions within the pleural cavity of children by Mr. T. H. Kellock, so that it cannot be regarded as pathognomonic of hydatid disease. The appreciation by the patient himself of the fremitus is also an unusual occurrence, and the suggestion put forward by M. Chauffard to explain it is a very plausible one. It would be worth while in any case of prominence of the chest such as this one to try for the sign in the manner described.

THE LIVERPOOL POLICE, INEBRIETY, AND THE ALIENS ACT.

THE report of the chief constable of Liverpool for the year 1908, recently laid before the watch committee of that city, contains observations upon the working of the Inebriates Act from the point of view of that executive authority which brings the inebriate before the magistrate and which has ample opportunity for observing the practical aspects of the sentence which follows. The statistics of Liverpool show that up to the time of the inquiry of the Departmental Committee of last year 113 persons had been committed there under the Inebriates Act of 1898. Of these, 17 were males and 96 females. After various periods of detention, 60 of them, including 8 males and 52 females, had been released, of whom 38 (4 males and 34 females) had since relapsed. Definitely proved failure to bring about any lasting result in so many of the cases treated at considerable expense is not a very encouraging result. The chief constable of Liverpool ascribes the lack of success to the difficulty of applying the Act in time. In his view, the persons upon whom reforming measures are tried are too often past cure. They are enormously benefited during the time that they are under restraint, but they are too far gone before committal to be able to resist temptation when restored to liberty, and he suggests that it should be possible to bring under the provisions of the Act those who are at an earlier stage in the downward road. He also criticises the practice of treating first convictions for drunkenness lightly, instead of trying to make the convicted person realise that he has committed an offence against the law of which he ought to be thoroughly ashamed. This is a matter for the consideration of magistrates who, we feel sure, are actuated by a desire to exercise clemency towards men or women, possibly young and certainly foolish, but not in the ordinary sense criminals, whereas, on the other hand, a severer attitude on the part of the bench may have a salutary effect in checking the formation of habits of excess. Another point of interest in the report before us relates to the passing of foreign emigrants and immigrants through Liverpool, of whom we are told that "every possible device for robbing and cheating them is tried. Since the United States and Canada became strict in their medical examination, especially with trachoma, smuggling rejected emigrants through the immigration bureaux, cheating them under the pretence of being able to cure them or to smuggle them through, has led to several prosecutions, and during this last year the one prosecution here under the Prevention of Corruption Act was obtained for an attempt to bribe a shipping company's doctor." It is consoling to learn that most of the offenders of this class are aliens themselves who can be deported, but we gather from a subsequent remark of the chief constable of Liverpool that he has little faith in such expulsion securing the permanent absence of the expelled criminal from this country. He may not return to Liverpool or to any other locality where he is known to the police, but he finds his occupation too profitable to be abandoned without seeking another field of operation in this hospitable island. We note also that the deporting of 13 undesirable aliens sent home from Liverpool cost the country about £148.

DIRECT APPLICATION OF THE X RAYS IN INTERNAL DISEASE.

IT is now well established that the x rays have a curative effect on superficial epitheliomata. But in deep-seated lesions, to which they cannot be directly applied, their value is considered doubtful, opinions varying, as our correspondence columns have shown. It has occurred to Dr. Carl Beck of New York to try the effect of applying the rays directly to the latter by means of an operation (eventration) and thus to put superficial and deep disease on the same level. In the *New York Medical Journal* of March 27th he has reported seven cases so treated. Though the number is small the results may be described as encouraging. A man, aged 40 years, had a large carcinoma of the pylorus which was slightly moveable. On its surface were several annular nodules attached to neighbouring parts, and there were several enlarged glands. Instead of performing pylorectomy, which he regarded as dangerous, Dr. Beck dissected the adherent area as far as was necessary to allow the diseased part to be pulled into the abdominal wound and sutured to the skin. No reaction followed the operation. Soon afterwards the x rays were applied daily for nine days. Then an erythematous spot began to form on the pylorus, but the skin showed no reaction. The application of the rays was stopped. Five days later the pylorus was of a pink colour. This became more marked, while the growth gradually disappeared. A week later the adhesions were divided and the pylorus was pushed back into the abdomen, which was closed. During the treatment small quantities of milk were given by the mouth and nutrient enemata. In the first week vomiting was frequent but was held in check by subcutaneous injections of morphine. The patient complained repeatedly of cramps in the region of the wound, which continued until three weeks after the operation. After this the rays were applied once a week for 15 months. The patient gained 18 pounds in weight and a growth could no longer be felt. In a second case, a woman, aged 43 years, had an induration on the anterior surface of the stomach and suffered from frequent hæmatemesis, pain, and cachexia. Exploratory laparotomy was performed on Feb. 4th, 1908, and revealed a large ulcer with indurated margins. The affected part of the stomach was sutured to the skin as in the first case. On the third day the x rays were applied. The patient progressed so well that she was discharged from hospital after four weeks. She gained 12 pounds in weight and has remained well ever since. In the third case, a cachectic man, aged 66 years, had a hard mass in the right iliac region of the size of the hand. Laparotomy revealed a nodular mass attached to the posterior part of the iliac fossa which was diagnosed as a fibrous carcinoma. Extirpation seemed belly of the muscle, resulting in cirrhosis, and the more acute infiltrative processes being at the extremities; much of the muscle was also quite normal. Of all the nerves examined those supplying the biceps were least affected, yet that muscle showed the myositic changes in a marked degree. These changes were clearly of an inflammatory nature, suggesting a direct toxic action of the alcohol on the muscle tissue.

SYPHILIS IN ITS RELATION TO DENTITION.

THERE has recently appeared in the columns of *Dental Cosmos* (November and December, 1908; January and Febuary, 1909, by Dr. Cavallaro) an exhaustive paper on the Relation of Syphilis to Dentition. The author has been able to confirm the discovery of Pasini that the spirochæta pallida is to be found in abundance in the dental follicle in proximity to the vessels and their walls. He shows that a curious modification of the lower ends of growing teeth can often be demonstrated in the form of a construction of the dental papilla which clinically corresponds to the atrophy of the tooth cusps so often seen. He states that at this part certain changes can be noted in the pulp tissue, the nuclei are better stained, and the infiltration of the embryonal cellular elements is more intense. He also has found in the dental follicles the following alterations—namely, endovasculitis, perivasculitis, and hæmorrhage. The lesions of syphilis, as far as the teeth are concerned, are usually seen in the permanent series on the incisors and first molars, and this he attributes to the fact that the maximum intensity of the virulence is during the last months of intra-uterine life and the first three months of extra-uterine life. In his opinion the deciduous teeth do not always escape, but the reason why they are not so likely to be affected is due to the fact that these teeth dentify between the seventeenth and eighteenth weeks, when syphilis rarely manifests itself, and, if it does, usually tends to abortion. In addition to the changes already referred to in the follicle, he finds certain histo-chemical alterations in the enamel and dentine. A detailed account of 38 cases is given, and to 22 of these illustrations of the teeth lesions are added. Dr. Cavallaro shows that in many cases not showing the typical Hutchinson's teeth other defects of the teeth are invariably present, and seems to regard these latter defects as pathognomonic of hereditary syphilis. With this we can hardly agree, because the type of lesions which he figures are all to be found in patients not showing a trace of congenital syphilis. An excellent bibliography is added to the paper.

THE annual dinner of the Indian Medical Service will be held at the Gaiety Restaurant, Strand, on Thursday, June 10th, at 7.45 P.M., Sir George Birdwood, K.C.I.E., in the chair, when the service will have the honour of entertaining General Sir O'Moore Creagh, V.C., K.C.B., Commander-in-Chief in India elect, as their guest. Officers intending to be present should communicate without delay with the honorary secretary, Lieutenant-Colonel P. J. Freyer, 27, Harley-street, W.

THE Croonian Lectures of the Royal College of Physicians of London will be delivered at 5 o'clock P.M. at the College on the following Tuesdays and Thursdays, June 15th, 17th, 22nd, and 24th. The lecturer, Dr. Lazarus-Barlow, has taken as his subject Radio-activity and Carcinoma.

AT the meeting of the London Education Committee on May 19th it was reported that the inquiries of the special committee into the cost of medical treatment of school children are being limited to the cost of treating eyes, ears, and skin diseases. Dental conditions are not included in the present reference.

A TELEGRAM from the Governor of Hong-Kong to the Secretary of State for the Colonies states that 6 cases of plague with 4 deaths were reported during the week ending May 15th.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF THE COUNCIL.

AN ordinary meeting of the Council was held on May 13th, Mr. HENRY MORRIS, the President, being in the chair.

Sir Shirley Forster Murphy and Mr. George Dancer Thane were introduced, and after signing the by-laws and making the required declaration were admitted Fellows of the College.

Mr. John Percy Lockhart Mummery was introduced and the PRESIDENT handed him a cheque for the amount of the Jacksonian Prize for the year 1908, together with a document declaratory of the award.

Mr. Arthur Swayne Underwood was introduced and the PRESIDENT handed him a cheque for the John Tomes Prize, together with a document declaratory of the award.

An undergraduate of Liverpool University, Mr. John Robert Douglas Webb, was appointed the second Begley Scholar.

The SECRETARY reported the death, on April 9th, at the age of 82 years, of Mr. Claudius Galen Wheelhouse, LL.D., a past member of the Council. The following vote of condolence was then carried:—

> That the Council hereby express their deep regret at the death of Mr. C. G. Wheelhouse, whom they highly esteemed as an able surgeon, keenly interested in all matters re [illegible] and the advancement of surgical science, a [illegible] and to the College they remember [illegible]
>
> That the Council desire also to [illegible] excellent personal qualities which [illegible] ship of all who knew him and to convey their sincere sympathy to Mrs. Wheelhouse and her daughter in their bereavement.

It was resolved to issue diplomas of Membership to 91 successful candidates and diplomas of the Licence in Dental Surgery to 30 successful candidates.

Mr. C. A. Ballance was elected a member of the Court of Examiners.

A letter was read from Mrs. Macloghlin offering to the College a work in bronze and marble by Alfred Gilbert, M.V.O., entitled "Mors janua vitæ." The offer was accepted with thanks.

The PRESIDENT stated that the vacancy on the Board of Examiners in Dental Surgery, occasioned by the retirement of Mr. Pearce Gould from the Court of Examiners, would be filled up at the next meeting of the Council.

MEETING OF HUNTERIAN TRUSTEES.

Lord WALSINGHAM presided at a meeting of the trustees of the Hunterian Collection which was held at the Royal College of Surgeons on May 12th. A committee appointed by the trustees at their previous meeting to examine into the state of the collection reported that they had duly inspected the collection and had found evidence of progress and improvement. The committee expressed their approval of a new system of box-indexing and descriptive labelling of specimens. Other trustees present were Mr. Henry Morris (President of the College), Sir John Tweedy, Dr. Norman Moore, and Dr. J. Kingston Fowler.

LIVINGSTONE COLLEGE.—Commemoration Day will be celebrated at Livingstone College, Leyton, E., on May 26th. The proceedings will commence at 3.30 P.M. The chair will be occupied by the Very Rev. H. Montagu Butler, D.D., Master of Trinity College, Cambridge. Professor A. Macalister will give an address on the Need of Elementary Medical Training for Missionaries in China, and Dr. M. A. Stein, the Asiatic explorer, will speak on the Importance of Elementary Medical and Surgical Knowledge in Far-off Lands. A special train will be provided from St. Pancras at 3.5 P.M., returning from Leyton (Midland) at 5.50 P.M. First-class tickets can be secured by sending 1s. to the Principal, or they may be obtained from a representative of the College on the platform.

LYNN THOMAS AND SKYRME FUND.

THE APPEAL AND THE RESPONSE

WE have received a report from Mr William Sheen, honorary secretary of the Lynn Thomas and Skyrme Fund, in which he summarises the results of the appeal to the medical profession which first appeared in our issue for March 21st, 1908, over the signatures of a numerous and representative body of leading physicians and surgeons It may be of interest to recall the circumstances of this appeal An action was laid against Mr J Lynn Thomas, C B, surgeon to the Cardiff Infirmary and Mr H E Skyrme of Cardiff by a plaintiff named Southern, who claimed £2000 against the defendants, being dissatisfied at the manner in which they had treated a fracture dislocation of the upper end of his humerus The case was heard at Cardiff assizes in 1905, when the jury disagreed A new trial took place in the King's Bench Division, London, in 1906, when the jury awarded the plaintiff £100 damages and mulcted the defendants in costs with the damages That these, with the costs of the defence, amounted altogether to a very large sum is shown by the fact that though part of the expenses were borne by the Medical Defence Union the defendants had to pay £3197 12*s* 3*d* This enormous fine was the penalty which the defendants had to pay for having treated the patient in a manner approved by a number of eminent surgeons who testified to that effect at the trials of the case A liberal response was made to the appeal, many of the subscriptions coming from colonial practitioners and practitioners resident abroad

The Fund was formally closed on July 31st, 1908 Since that date a few additional subscriptions have been received and the gross amount of the Fund, with interest, is now £1788 11*s* 6*d*. All the details of the subscriptions have been published, lists appearing from time to time in THE LANCET and the *British Medical Journal* The amounts of individual subscriptions have varied from £10 10*s* to 2*s* 6*d* An analysis of the subscriptions appears in the appended statement of accounts 1663 subscriptions were received from individuals, while 29 medical societies and 14 branches or divisions of the British Medical Association sent subscriptions from their general funds To the honorary secretaries of these bodies Mr Sheen wishes us to express his sincere thanks for their valuable support The expenses of collecting the Fund were £176 8*s* 9*d* A great amount of correspondence was involved, necessitating much circularising,

men concerned will be reimbursed to the extent of half of his expenditure The result cannot be regarded as otherwise than satisfactory The medical profession is not a rich one The enormous mass of correspondence which has come to hand shows a feeling of universal sympathy with the two gentlemen concerned and approval of the methods of treatment they employed Many letters of sympathy have been received from those who regret their inability to contribute

THE PRESENTATION

The presentation of the Fund will be made at Cardiff on June 4th next by M J Lucas Championnière, President of

M Lucas Championnière

under the auspices of the

odern Treatment of Fractures To this address, besides the local members of the medical profession, all subscribers to the Fund will be invited In the evening a dinner will be given in the course of which the presentation will be made No more appropriate member of our profession could be chosen to make the presentation than M Lucas Championnière, not only because of his position as President of the International Surgical Society but because he is the pioneer of the present rational treatment of fractures It was the carrying out of the methods of treatment advocated and practised by M Lucas Championnière that helped to involve Mr Lynn Thomas and Mr Skyrme in litigation The sympathy shown by M Lucas Championnière and his approval of the methods employed have been undoubted from the first, and his opinion was expressed in no uncertain terms in an article which he contributed to the *British Medical Journal* on March 28th, 1908 The visit of so distinguished a surgeon to Cardiff is a matter of congratulation, and it is hoped that members of the profession will unite in large numbers to give him a cordial welcome and express in every way possible their appreciation of his visit His reception will be of a civic character, and he will be the guest of the Lord Mayor

THE STATEMENT OF RECEIPTS AND EXPENDITURE

The Honorary Secretary's audited statement of receipts and expenditure is as follows —

Receipts

	£	s	d
To 974 Subscriptions received by Honorary Secretary direct	1365	14	0
" 550 Subscriptions received through Honorary Secretaries of Branches and Divisions of the British Medical Association	165	9	0
" 139 Subscriptions received through Honorary Secretaries of Medical Societies	37	12	0
" 14 Subscriptions from General Funds of Branches or Divisions of the British Medical Association	65	8	0
, 29 Subscriptions from General Funds of Medical Societies	113	12	6
, 3 Subscriptions from Hospital Staffs	11	19	0
Some Indian Sympathisers"	1	1	0
, Interest received from Bank Deposit	26	16	0
	£1788	11	6

Expenditure

	£	s	d
By Printing and Stationery	64	5	9
, Stamps	61	3	10
" Incidentals	4	5	11
, Clerical work	44	2	7
" Expenses of Circulars Western Australian Branch of the British Medical Association	1	9	8
Translation of Protest	1	1	0
	176	8	9
, Balance at Bankers	1612	2	9
	£1788	11	6

I have examined the above account with the Hon Secretary's books, vouchers &c and certify it to be correct

Cardiff May 12th 1909 R H MARCH F C A.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary Comitia was held on May 13th, Sir R. DOUGLAS POWELL, Bart, K C V O, the President, being in the chair

Those gentlemen who had been elected as Fellows of the College at the previous Comitia were admitted John Edward Squire, C B, M D Lond, Theodore Stacey Wilson, M D Edin, Charles John Macalister, M D Edin, George Harold Arthur Comyns Berkeley, M B Camb; Robert Oswald Moon, M D Oxon, Clive Riviere, M D Lond, Oliver Key Williamson, M D Camb, Francis Arthur Bainbridge, M D Camb, John Shields Fairbairn, M B Oxon, Otto Fritz Frankau Grunbaum, M D Camb, Joseph Shaw Bolton, M D Lond, Charles Bolton M D Lond; and Llewellyn Caractacus Powell Phillips, M D Camb

A communication was received from Dr E Liveing resigning his office of Registrar and the membership of the Committee of Management

The PRESIDENT regretted that there was no option but to accept the resignation and expressed in laudatory terms the great services that Dr Liveing had rendered to the College

The following motion was then proposed by Sir W S CHURCH, seconded by Dr NORMAN MOORE and carried unanimously —

The PRESIDENT then dissolved the Comitia.

exceptional quality at their disposal, and they have had the sense to realise what many English spas have been too long in realising—that if their "cure-house" is to compete with more famous Continental rivals the patient must be the central figure in their community, and the life of the place must be subordinated to the requirements laid down by his physician for his welfare. But the visitors are not all invalids at Woodhall, and life need not be dull for the holiday maker who only needs restful recreation. For him there have been provided tennis courts, a cricket ground, a croquet ground, a band-stand, and above all these a well-kept golf links with sand and heather bunkers among pine and larch woods that form a background. Near the golf club's quarters is the Clevedon club-house, of which we are able to give an illustration. The club of which Fig. 2 is an illustration is a social club for which visitors are eligible. But of all its attractions Woodhall Spa takes its waters the most seriously, and its visitors in search of relief will be well advised to follow its example.

In conclusion, we wish to express our thanks to Dr. Calthrop and his fellow directors for the hospitality and courtesy which was extended to our representative during a very pleasant and interesting visit.

SANITATION IN INDIA.

V.[1]—JAILS (*continued*).

North-West Frontier Province.

THE administration report of the jails of the North-West Frontier Province for 1907 is furnished by Lieutenant-Colonel G. W. P. Dennys, I.M.S., the officiating administrative officer of the province. The judicial statistics show that the jail population remaining on Dec. 31st was 1307, or 144 more than on the corresponding date of 1906. It is very satisfactory to note that the reformatory school at Delhi has been made available for the reception of youthful offenders of the North-West Frontier Province, so that it is to be hoped that in the future such prisoners will not be sent to jail, where the baneful influence of prison life has the effect of doing them more harm than good. A point which is well brought out in the report is that with respect to the length of sentence of the prisoners. It is shown that the percentage is highest in the case of prisoners sentenced to imprisonment up to one month. Attention is drawn to this, because it is very difficult to find any suitable form of hard labour for short-term prisoners, the result being that these short sentences are not sufficiently deterrent, and so jail life is apt to lose much of the terror that it ought to hold in the minds of the free population. Colonel Dennys insists that corporal punishment, when permissible, is much preferable to short sentences.

With respect to the internal economy of the jails, the upper subordinates have worked with much greater zeal and energy, and this fact is no doubt due to the improvement in the pay and prospects of jailers and assistant jailers of the province effected by the reconstitution of the jail service in 1907. The scales of pay and grade sanctioned for the Punjab have been introduced into the province, with the addition of a frontier allowance to jailers but not to assistant jailers, as it was thought at the time that educated men of respectable families would be induced to take service in the jail department for the prospects of being promoted to jailerships. This expectation, however, has not been realised, so that the addition of frontier allowances will most probably have to be granted to assistant jailers as well as to the jailers.

With respect to the vital statistics of the jails, Colonel Dennys notes that the condition as regards overcrowding is satisfactory. This diminution of overcrowding is doubtless due to the wise system introduced by this officer in 1906 of making superintendents always keep in hand a list of prisoners whose transfers have been sanctioned, but who would only be despatched in the event of overcrowding seeming imminent by a rapid rise in the jail population. He points out with reference to this measure that a larger amount of extra work is thrown on the jail staff by the constant preparation of long lists of prisoners for transfer from one jail to another, whilst also great inconvenience to the police is caused in having to arrange at frequent intervals for the necessary guards to accompany the prisoners on transfer, which are often required at short notice, whilst such transfers also entail much expense. For the money thus spent a great deal of the extra jail accommodation required in the province could have been provided. The remedy, of course, lies in increasing the accommodation in the jails; such increase has been sanctioned by the Chief Commissioner of the province in the case of the Dera Ismail Khan jail, and it is to be hoped that this sanction will be extended to the Bannu and Kohat jails in the future.

The supply of drinking water at all the jails was ample and good, but might be made still more satisfactory in some of the jails if pipe water were introduced in the place of surface wells, as at Dera Ismail Khan and Bannu. The admissions into hospital of average strength were 1242 per 1000, the daily average sick 35, and deaths from all causes 17·47, as contrasted with the figures for 1906, 1485, 35, and 23·47 respectively. The health of the prisoners on the whole was therefore better than in the previous year, although the death-rate in Dera Ismail Khan of 29·65 per 1000 was very heavy. With respect to the different diseases, the admissions for malarial fevers fell from 927 per 1000 in 1906 to 489 in 1907. No deaths from malaria occurred. Quinine was issued to all convicted prisoners in 15-grain doses of the liquid solution every fifth and sixth day from July 1st to the end of the fever season. This issue conferred a considerable immunity against malaria, which, however, is not perceptible until after the first month of treatment.

There were 11 admissions for tubercle with four deaths. Colonel Dennys wisely advises, if possible, to release prisoners suffering from tubercle of the lung on the ground of bodily infirmity, under paragraph 535 of the Jail Manual, as there are no satisfactory arrangements for treating such cases in the jails, and their presence is always a source of danger to other prisoners. The highest mortality from disease was shown in the cases of pneumonia admitted, the case mortality being 25 per cent.; this high mortality was only to be expected after the severe malaria prevalent in the autumn of 1906. Diarrhœa gave an unusually heavy and excessive number of admissions over those of the two previous years, and inquiries as to the causation of this excess are being made. Colonel Dennys records high praise to the superintendent of his office, Mr. E. Penn David, and to his clerks, and the report then closes with the usual appendices. In reading this report we cannot help being struck with the faculty so well possessed by the administrative medical officer of giving all his facts in well chosen, concise language.

United Provinces.

Lieutenant-Colonel S. H. Henderson, I.M.S., the officiating Inspector of Prisons for the United Provinces, furnishes the report for 1907. The jail population in these provinces was normal until late in the year, when the complete failure of the *rabi* crops had its effect, and in certain districts the under trial population began rapidly to rise at the end of the year, so that an increase of 1363 prisoners for the year 1907 resulted over the number for 1906. With regard to the prisoners generally, it is satisfactory to note that the number of juveniles under 16 years was 154, as compared with 191 in 1906. This satisfactory reduction in their number is probably due to the more summary punishment by whipping, but also may be owing to the increasing disinclination of magistrates to send children to jail. These juveniles are not allowed to mix with ordinary prisoners; they are taught reading, writing, and arithmetic, and are drilled regularly in addition to ordinary convict labour, all of which proceedings are very wise. With regard to the treatment of non-habitual youths between the ages of 16 and 20, they have always been a very difficult problem to deal with. They can be kept separate at night in cubicles in special wards, but it is found practically impossible to prevent their coming into contact with other persons only too ready to influence them for evil during the day. Lieutenant-Colonel Mactaggart, the predecessor of Lieutenant-Colonel Henderson, wisely suggested, as at least a partial remedy, the opening of a special juvenile jail for boys of this class, and recommended the use of the old reformatory school building at Bareilly, This not being in use, for conversion into such a jail.

---

[1] Nos. I., II., III., and IV. were published in THE LANCET of April 10th (p. 1067) and 24th (p. 1199), and May 1st (p. 1269) and 15th (p. 1412), respectively.

scheme, which has been sanctioned by the Lieutenant-Governor, would seem to answer admirably the purpose involved, for by it the accommodation is sufficient, hard work and rigid discipline can be insisted on, as it is near the Bareilly central jail, and so can be efficiently supervised by the superintendent of that jail; each boy will be taught, according to his caste and previous occupation, a handicraft which he can follow on his release. Their physical development will be favoured by the drill, and the teachers and warders will be specially selected. The Inspector-General hopes that by these means permanent good results will accrue to the youths [illegible] admitted, there was a slig [illegible] of age, due no doubt to [illegible] which caused some of those who could not support themselves to resort to petty thefts. Many of these old prisoners were in truth more fit subjects for admission to a poor house than to a jail. The progressive rise in the number of [illegible] 1907; this is probably [illegible] remedy would seem t[illegible] of jail life by making it as unpleasant as possible by more frequent combination of solitary sentences with rigorous imprisonment. Cubicle barracks, which are still wanting in many of the jails of this province, are very desirable.

With respect to the special industries carried on in these jails, these embrace moonji matting, blanket weaving—the latter in the Bareilly jail being probably the exciting cause of an outbreak of anthrax, as on its occurrence all wool was ordered to be boiled and treated with lime, when no more cases occurred—carpet and durrie weaving, tent making, basket making, cloth weaving, oil pressing, tile making, printing, carpenters' and blacksmiths' work, with building operations. All the jail factories were worked at a profit.

Respecting the vital statistics of these jails, there was not during 1907 much difference observable from those of 1906. The rates of admissions per 1000, of sick, and of deaths were for 1907, 603·0, 28·7, and 15·0, as compared with 602·7, 26·5, and 16·5 for 1906. As regards the chief diseases, we note that a very fatal epidemic of influenza with pneumonia occurred in the Agra jail, there being 45 admissions with ten deaths, which is a very high rate, whilst in the whole province there were 278 admissions with 80 deaths from pneumonia. At Lucknow jail there was a prevalence of cellulitis, the primary cause of which was never satisfactorily made out. Special precautions were taken in obtaining dry earth for the latrines and other purposes, and under these precautions the disease began gradually to disappear. Tl[illegible] tion of all [illegible] of beri-ber[illegible] which was also not discovered; the jail is an excellent one, with no overcrowding, and in very good sanitary condition. The use of rice was stopped early in October and is not likely to have caused the epidemic, which began later. This disease was new to the jails in that province. The symptoms were chiefly œdema of the feet and legs, [illegible] cases. Although the opinion is stated that rice was not the cause of the disease as it was stopped early in October, yet there seems to have been one case at least of the disease early in September before the rice rations were abolished, so that this opinion is not altogether conclusive against such a cause. [illegible] to preve[illegible] nullified [illegible] they breed freely. The Inspector-General thinks the more systematic prophylactic use of quinine in the unhealthy season of the year might be more freely tried in some of the unhealthy jails of the province with good effect. The report concludes with the usual appendices. Colonel Henderson also gratefully acknowledges the excellent work done by his head assistant, and by his head and other clerks.

Province of Eastern Bengal and Assam.

The report of the jail administration for Eastern Bengal and Assam for 1907 is furnished by the Inspector-General of Prisons, Lieutenant-Colonel R. R. Wei[illegible] gives the following details. The total numb[illegible] admitted during the year was 36,382, against [illegible] the daily average being 8098 against 7726 in the preceding year. This increase of 372 is attributed to longer average of length of sentences, as generally there has been a decrease in crime. We again notice that there is no provision in any jail in the province for the special and complete separation of juveniles from the general jail population; it is to be hoped that the authorities concerned will awaken to the desirability of this procedure for the sake of the future of these juveniles. The report gives all particulars regarding sex, religion, previous occupation, education, nationality, and terms and nature of imprisonment. With regard to the [illegible] of jail accommodation, overcrowding occurred in [illegible] the jails of the province during the year, particularly [illegible]ase of those under trial; this was partially overcome by placing surplus prisoners in temporary sheds, worksheds, and verandahs.

Regarding the vital statistics for 1907, the ratio per 1000 of admissions into hospital for 1907 was 837·03, the daily average sick 35·35, and the mortality 28·40, as contrasted with 876·43, 40·14, and 27·95 for 1906. The daily average number of prisoners mentioned above was the highest for the past ten years, yet the hospital admissions were lower than in any of the preceding ten years, except those for 1904 and 1906, and that in spite of almost general overcrowding; the cases actually admitted, however, were of a severe type, judging from the rate of mortality. With respect to the nature of the diseases met with, dysentery, we are glad to see, showed a decrease; there was a rise in malarial fever—viz., 1904, against 1669 in 1906. The number of deaths, however, fell from 25 to 21. Beri-beri was reported present in four jails; there were three admissions for enteric fever, all of which ended fatally. Epidemic dropsy caused 44 admissions, with three deaths; the Inspector-General reports that segregation, with a change to a more liberal diet, effectively checked the disease. The bad effect of influenza with overcrowding was shown in the Feridpur jail, where the health was the worst since 1900. Dysentery, ague, pneumonia, and tuberculosis very greatly prevailed in this jail.

Many improvements bearing on sanitation have been carried out in 1907; thus ventilation, drainage, conservancy, water-supply, and cooking arrangements have all been bettered, and other important matters attended to, such as the clearing away of surrounding jungle from certain jails, the removal of insanitary cattlesheds, and improvement of the ground level. The report concludes with the various methods by which the prisoners were employed and the financial questions involved. The Inspector-General finally mentions with praise the work of the various superintendents, and especially draws attention to the successful management of the Barisal jail and the remarkable diminution in the sickness and mortality there, due "to the careful and unremitting supervision of Captain O. St. John Moses, I.M.S." Only those who have had charge of an Indian jail can fully appreciate what these words of praise signify. The usual statistical tables complete the report.

Looking Back.

FROM

THE LANCET, *SATURDAY*, May 21st, 1831.

CRYSTALLISED IODURET OF LEAD.

M. CAVENTOU, of Paris, has discovered the following simple method of obtaining this valuable medicine in a crystalline form. On adding any solution of lead to a solution of the hydriodate of potassa, a canary-coloured precipitate of a minutely crystalline texture is thrown down. This precipitate has hitherto been considered as insoluble in water. M. Caventou has found that it is abundantly dissolved in hot water, and from this solution it crystallises on cooling in crystals of considerable size and of the utmost beauty. We have, on repeating this process, been astonished at the singular splendour of the product thus obtained. It so strongly resembles highly polished gold, that several persons have mistaken it for that metal. No [illegible]-sis has yet been made of the respective [illegible]e and lead in this compound. By calcula[illegible] to be composed of iodine 100, lead 85-5.

M. Caventou's improvement is described in the *Lancette Française*.

The clinical experiments now performing by MM. Cottereau and Verdet de Lisle, at the Hopital de la Pitie, appear to indicate, that of all the preparations of iodine, this possesses, in the highest degree, the property of resolving scrofulous and scirrhous engorgements: at least this may be inferred from the remarkable and rapid improvement experienced by the patients in whom it has been tried, and who had all been previously using iodine and the hydriodate of potassa, both internally and externally, without success. M. Guersent has also found it of the most signal advantage in several cases at the Hôpital des Enfans.—*Journal Hebdomadaire.*

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8240 births and 4322 deaths were registered during the week ending May 15th. The annual rate of mortality in these towns, which had declined in the eight preceding weeks from 22·1 to 14·1, further declined to 13·7 in the week under notice. During the first six weeks of the current quarter the death-rate in these towns averaged 15·4 per 1000; the rate in London during the same period did not exceed 14·9. The lowest recorded annual death-rates in these towns last week were 5·9 in Handsworth, 7·2 in Bournemouth, 7·5 in East Ham, and 8·0 in Northampton; the rates in the other towns ranged upwards, however, to 22·9 in Oldham, 23·3 in Bootle, 24·1 in Coventry, and 24·7 in Wigan. In London the recorded death-rate during the week did not exceed 13·1 per 1000. The 4322 deaths from all causes in the 76 towns last week showed a further decline of 140 from the numbers returned in recent weeks, and included 394 which were referred to the principal epidemic diseases, against numbers declining from 593 to 445 in the five preceding weeks; of these 394 deaths, 170 resulted from measles, 95 from whooping-cough, 44 from scarlet fever, 37 from diarrhœa, 29 from diphtheria, and 19 from "fever" (principally enteric), but not one from small-pox. The 394 deaths from these epidemic diseases in the week under notice were equal to an annual rate of 1·2 per 1000, against rates declining from 1·9 to 1·4 in the five preceding weeks. No death from any of these epidemic diseases was registered last week in Gateshead, Plymouth, Northampton, Rochdale, York, or in eight other smaller towns; the annual death-rates therefrom ranged upwards, however, to 3·2 in in Salford, 4·5 in Bootle, 5·2 in Wigan, and 7·5 in Wolverhampton. The fatal cases of measles in the 76 towns, which had steadily declined in the eight preceding weeks from 438 to 198, further fell last week to 170, but caused death-rates ranging upwards to 2·2 per 1000 in Warrington, 3·0 in Bootle, 3·5 in Wigan, and 7·5 in Wolverhampton. The deaths from whooping-cough, which had been 131, 113, and 109 in the three previous weeks, further declined last week to 95, the highest death-rates from this disease being 1·3 in Willesden and Coventry, 1·5 in Middlesbrough, and 1·6 in St. Helens and in Swansea. The 44 fatal cases of scarlet fever showed a slight increase upon recent weekly numbers, and caused the highest death-rates, 1·1 in Blackburn and 1·3 in Merthyr Tydfil. The 37 deaths attributed to diarrhœa were fewer by five than the number in the previous week. The 29 fatal cases of diphtheria were considerably below the number returned in any previous week of this year, and showed no marked excess in any of the towns. The 19 deaths from "fever" showed an increase of 12 upon the low number in the previous week, and included three in Hanley, equal to an annual rate of 2·3 per 1000. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had decreased in the ten preceding weeks from 2873 to 2175, had further declined to 2173 at the end of last week; 313 new cases were, however, admitted to these hospitals during the week, against 265, 305, and 309 in the three preceding weeks. The registered deaths in London referred to pneumonia and other diseases of the respiratory organs, which had declined from 341 to 212 in the four preceding weeks, were 222 last week, and 33 below the corrected average number in the corresponding week of the five years 1904–08. The deaths in London referred directly to influenza, which had been 45, 32, and 16 in the three preceding weeks, rose again to 20 in the week under notice. The causes of 26, or 0·6 per cent., of the deaths registered in the 76 towns during the week were not certified either by a registered medical practitioner or by a coroner. The causes of all the deaths registered during the week were again duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, and in 55 other smaller towns; the 26 uncertified causes of death included three each in Birmingham, Sunderland, and Gateshead, and two each in Liverpool, Sheffield, and South Shields.

HEALTH OF GLASGOW AND EDINBURGH.

The annual rate of mortality in Glasgow, which had been equal to 19·3, 17·4, 18·1, and 16·3 per 1000 in the four preceding weeks, further declined to 15·2 in the week ending May 15th. During the first six weeks of the current quarter the death-rate averaged 17·7 per 1000, whereas the mean rate during the same period did not exceed 14·9 in London and 16·6 in Edinburgh. The 254 deaths from all causes in Glasgow last week showed a decline of 19 from the number in the previous week, and included 23 which were referred to the principal epidemic diseases, and were fewer by 19 than those returned in the preceding week. These 23 deaths were equal to an annual rate of 1·4 per 1000. The eight fatal cases of whooping-cough showed a marked decline from the numbers in recent weeks. One death from cerebro-spinal meningitis was registered. The deaths referred to diseases of the respiratory organs, which had declined in the four preceding weeks from 71 to 50, rose again to 55 in the week under notice. The 154 deaths registered during the week included 78, or 30·7 per cent., which were recorded in public institutions, against 92 and 91 in the two previous weeks. The causes of 13, or 5·1 per cent., of the deaths registered last week were unspecified or uncertified, whereas in London the causes of all but one of the 1216 deaths registered last week were duly certified. In Edinburgh the annual rate of mortality, which had been equal to 18·5, 17·2, and 16·3 per 1000 in the three preceding weeks, further declined to 14·2 in the week ending May 15th. During the first six weeks of the current quarter the death-rate averaged 16·6 per 1000, the mean rate during the same period in Glasgow being equal to 17·7. The 97 deaths from all causes last week in Edinburgh showed a further decline of 14 from the numbers in recent weeks, and included but four which resulted from the principal epidemic diseases, all of which were fatal cases of whooping-cough. These four deaths were equal to an annual rate of 0·6 per 1000, against 2·6 and 1·6, the rates from these principal epidemic diseases in the two preceding weeks. The 14 deaths referred to diseases of the respiratory organs corresponded with the number in the previous week. Five of the deaths in the week were the result of violence. Of the 97 deaths registered during the week, 37, or 38·2 per cent, occurred, in public institutions, against 27 and 44 in the two preceding weeks. The causes of seven, or 7·2 per cent., of the deaths registered during the week were not certified; while in Glasgow the proportion of uncertified causes did not exceed 5·1 per cent.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had steadily declined in the four preceding weeks from 27·7 to 18·8 per 1000, further fell to 18·5 in the week ending May 15th. During the first six weeks of the current quarter the death-rate averaged 22·8 per 1000, whereas the mean rate during the same period did not exceed 14·9 in London and 16·6 in Edinburgh. The 141 deaths of Dublin residents from all causes during the week under notice showed a further decline of three from the numbers returned in recent weeks, and included 11 which were referred to the principal epidemic diseases, against 16 and eight in the two preceding weeks. These 11 deaths were equal to an annual rate of 1·4 per 1000, the death-rate from these principal epidemic diseases in the same week being equal to 1·2 in London and 0·6 in Edinburgh. Of the 11 deaths from these epidemic diseases in Dublin last week, five resulted from whooping-cough, three from measles, two from "fever," and one from diarrhœa, but not one either from scarlet fever, diphtheria, or small pox The fatal cases of whooping cough measles, and "fever" exceeded the numbers in the previous week The 141 deaths registered last week included 21 of infants under one year of age and 51 of persons aged upwards of 60 years, the deaths of elderly persons considerably exceeded the number in the previous week Six inquest cases and two deaths from violence were registered last week, and 53, or 37 6 per cent, of the deaths occurred in public institutions The causes of four, or 2 8 per cent, of the deaths in Dublin during the week were not certified either by a registered medical practitioner or by a coroner, in London the causes of all but one of the 1216 registered deaths were duly certified, while in Edinburgh the proportion of uncertified causes was equal to 7 2 per cent

THE SERVICES

ROYAL NAVY MEDICAL SERVICE

THE following appointments are notified —Staff Surgeons A C Bean to the *Pembroke*, additional, for disposal, J Martin to the *Magnificent*, and H L Geoghegan to the Royal Marine Infirmary, Deal

ROYAL ARMY MEDICAL CORPS

Lieutenant Colonel John Carmichael is placed on retired pay (dated May 5th, 1909)

Colonel H J R Moberly has been appointed officiating principal medical officer, Presidency and Assam Brigades, and Lieutenant Colonel F P Nichols has been appointed to the command of the Station Hospital, Jullundur

INDIAN MEDICAL SERVICE

The King has approved of the retirement of the following officer Colonel David Wilkie (dated April 2nd, 1909)

MILITIA

Royal Army Medical Corps

Captain William Fletcher, D S O, resigns his commission (dated Sept 20th, 1908)

TERRITORIAL FORCE

Royal Army Medical Corps

Lowland Mounted Brigade Field Ambulance The promotion to a Lieutenant-Colonelcy of Major Robert T Halliday and to a Majority of Captain Hugh W Thomson bears date April 1st, 1908

2nd London (City of London) Field Ambulance Percy Cecil Parker Ingram to be Lieutenant (dated March 30th 1909) Haldinstein David Davis to be Lieutenant (dated April 16th, 1909)

4th Scottish General Hospital Lieutenant Colonel (Honorary Surgeon Colonel, Retired List, Volunteers) Alexander Napier, from the Mobilisation List, to be Lieutenant Colonel, with the honorary rank of Surgeon Colonel (dated March 22nd, 1909)

1st Home Counties Field Ambulance Captain William J [illegible]

Volunteer Battalion, The Welsh Regiment, to be Lieutenant Colonel, with the honorary rank of Surgeon Colonel, with precedence as in the Volunteer Force (dated April 1st, 1908) Ewen John Maclean to be Major (dated March 11th 1909)

Attached to Units other than Medical Units—Lieutenant George McKellar to be Captain (dated April 1st, 1908) Major John F Tabb to be Lieutenant-Colonel (dated April 4th, 1908) Captain Herman Stedman to be Major (dated Nov 23rd, 1908)

For attachment to Units other than Medical Units—Robert Bruce to be Lieutenant (dated March 17th 1909) Alfred Edward Arthur Carver to be Lieutenant (dated March 30th, 1909) Herbert Pye Smith Devitt to be Lieutenant (dated March 30th 1909) Donald Sage Sutherland to be Lieutenant (dated March 30th, 1909) Surgeon Lieutenant-Colonel and Honorary Surgeon-Colonel Edward Morton Garstang from the 2nd Volunteer Battalion The Loyal North Lancashire Regiment, to be Lieutenant Colonel, with the honorary rank of Surgeon Colonel with precedence as in the Volunteer Force (dated April 1st, 1908) Supernumerary Captain Frederick Lace from the 4th Battalion The Prince Albert's *(Somersetshire Light Infantry)*, to be Major (dated March 1st 1909) James McGlashan to be Lieutenant (dated March 31st 1909) Frederick William Higgs to be Lieutenant (dated April 1st 1909) James Alexander Raeburn to be Lieutenant (dated April 13th, 1909) Robert Vernon Giraud Monckton to be Lieutenant (dated April 16th, 1909)

Officers Training Corps

The undermentioned officer to be Captain —Edinburgh University Contingent Senior Division Lieutenant John M Darling (dated July 17th, 1908)

EXAMINATION FOR SURGEONS IN THE ROYAL NAVY

At the entrance examination for Surgeons in the Royal Navy, completed on May 14th, 32 candidates presented themselves for 15 vacancies Two gentlemen withdrew eight were rejected for physical defects and of the remaining 22 18 obtained qualifying marks The following is the list of successful candidates —

	Marks		Marks
K H Hole	2151	J S Orwin	1635
G F Syms	1963	J Barrett	1645
A A Sanders	1933	H W Nichols	1638
M P Fitzgerald	1927	R P M Roberts	1505
J Hadwen	1914	M G Malcolm	1495
H F Briggs	1900	H C Devas	1420
G A Jackson	1734	H Burns	1405
W Miller	1710		

The above named gentlemen will undergo a course of instruction in special subjects at Haslar Hospital, on the completion of which another examination will be held, and prizes consisting of a gold medal a silver medal, and three Navy regulation pocket cases awarded The final position on the list will be determined by the combined results of the London and Haslar examinations

THE TERRITORIAL DECORATION

The King has conferred the Territorial Decoration upon the undermentioned officers of the Territorial Force who have been duly recommended for the same under the terms of the Royal Warrant dated August 17th, 1908 —

London District Royal Army Medical Corps Major John Frederic Tabb

Scottish Command Royal Army Medical Corps Colonel John Scott Riddell, M V O

Western Command Royal Army Medical Corps Sanitary Service Lieutenant Colonel Nathaniel Edward Roberts

THE TENURE OF ROYAL ARMY MEDICAL CORPS APPOINTMENTS

The May issue of the *Journal of the Royal Army Medical Corps* contains a communication from the Director General of the Army Medical Service relating to the tenure of Royal Army Medical Corps appointments Some of the appointments may now be held for three years with a possible extension to five years and some for four years only In a future issue of THE LANCET we hope to deal more fully with this important communication from the Director General of the Army Medical Service, which is published for general information

THE INCOME TAX AND INDIAN OFFICERS

In the House of Commons on May 13th Mr Smeaton asked the Chancellor of the Exchequer whether it was his intention to continue the exemptions and abatements on their small home incomes to Indian civil and military officers resident on duty in India who were in receipt of salaries from the Indian Government Mr Hobhouse replied that it was not intended to exempt Indian civil and military officers resident in India and receiving salaries from the Indian Government from the proposed obligations on persons resident abroad to pay full income tax

THE ORDER OF ST JOHN OF JERUSALEM IN ENGLAND

His Royal Highness the Prince of Wales has nominated Major R J Blackham R A M C, an Honorary Associate of the Order of St John of Jerusalem in England

---

ROYAL BRITISH NURSES' ASSOCIATION —The annual meeting of this association will be held at 3 30 P M to day Friday May 21st at the Imperial Institute H R H The Princess Christian of Schleswig-Holstein has graciously signified her intention to preside

Correspondence.

"Audi alteram partem."

THE MEDICAL TREATMENT OF LONDON SCHOOL CHILDREN.

To the Editor of THE LANCET.

SIR,—I cannot help thinking that your correspondents have misapprehended the intentions of the London County Council in the above matter. They write as if it were the wish of the Council to get the school children treated by the honorary staffs of the hospitals, and treated gratuitously. So far as I can discover this misrepresents entirely the view of the Council. What is desired is (1) to utilise the accommodation and equipment of the out-patient departments of the hospitals at times when these are not otherwise in use and to pay a reasonable rent for the privilege of doing so; and (2) to appoint special salaried officers to attend the school children in the accommodation thus provided. The honorary staffs of the hospitals would not be asked to undertake the work, but it certainly would be an advantage if the special paid officers could act under the supervision of members of the hospital staffs, for in that case the Council would be able to waive the question of inspection.

There is here no question of "subsidising" the hospitals; the latter simply rent out rooms at hours when they are not wanted for the ordinary out-patient work and the salaries of the special medical officers need not be paid through the hospitals at all. In any case, the principle of paid clinical assistants is no new one and is already in operation at some hospitals.

If, of course, the out-patient department of any hospital is working at such high pressure that all of its rooms are in use all day that settles the question as far as that particular institution is concerned, but this is certainly very far from being the case with those with which I am best acquainted.

The case against school Clinics seems to me very strong. If the Council is driven to adopt them it would mean setting up what are virtually a number of small children's hospitals, or, at the least, out-patient departments, all over London at great cost to the rate-payers. These would inevitably compete with the hospital out-patient departments and would draw away from them a large amount of valuable clinical material.

Observe, too, that this increased expenditure on bricks and mortar is to be undertaken in spite of the fact that the number of *children in the London school area is declining*; that the number of out-patients at some at least of the hospitals is also declining; and that within a year or so of the establishment of the Clinics the arrears of children needing treatment would have been worked off and the number to be dealt with weekly would have sunk to comparatively insignificant proportions. The Clinics would then have become of the nature of white elephants, and in order to justify their existence would probably start treating general medical and surgical ailments in addition to those special troubles for dealing with which they were first called into existence.

I have said nothing of the legitimate interests of the general *practitioner as I do not think these are likely to* suffer more under one scheme than under the other. If the Clinics are established they will certainly need to be officered by specialists and the appointments on them are likely to go to junior consultants who are not yet attached to any honorary staff. It is not probable, therefore, that any of the money to be paid for treatment at the Clinics will find its way to the practitioner. As to what is to be done in the case of those children whose parents can pay for private medical treatment there is need for discussion, but if the Council is unjust enough to treat these at the expense of the ratepayers the establishment of Clinics would only facilitate such an intention. I hope, therefore, that before it is too late the hospitals will reconsider their position and try to meet the Council half way, for if the alternative of school Clinics is adopted I feel convinced that it will be the members of the hospital staffs who, next to the ratepayers, will be the first to regret it.

I am, Sir, yours faithfully,
May 19th. ROBERT HUTCHISON.

To the Editor of THE LANCET.

SIR,—Those of us who are members of the honorary medical staffs of the metropolitan hospitals ought to owe you a debt of gratitude for opening your influential columns to a discussion of this important question. I have reason to believe that some of the hospital secretaries, as well as several members of the boards of management, are greatly tempted by the alluring bait of a little extra money—the proposed subsidies or capitation grants—to fall in with the wishes of the "Education Department of the London County Council"; and there can be little doubt that if the honorary staffs of the various hospitals do not make a firm stand our services will be still further exploited to the detriment of the general practitioners of the respective neighbourhoods. For many years I have been calling attention to the unwarrantable demands of the late "School Board" and of their successors, the "Education Department of the County Council," on the gratuitous services of the hospital staffs, and I personally have always declined to sign their official documents or to do work for which their own officers should be responsible. On the present occasion I have distinctly stated to the authorities of my hospital (1) that it is not my intention to treat any cases which may be sent to the hospital by the school nurses or inspectors which do not seem to belong to the hospital class; (2) that not being an officer of the London County Council I shall not sign their official documents or perform the duties of a sanitary or medical officer of the department; and (3) that I shall not be dictated to as to my methods of treatment by any such outside body as the London County Council. It seems that the cases of ringworm are to be sent to my department "*for x ray treatment*"; it so happens that I decline to treat all cases of this disease by that method—I know I am not "in the fashion"—as I get excellent results in early cases in other ways; and I regret that I cannot agree with the writer of your leading article on the Roentgen Ray Treatment of Ringworm (May 15th), that "so far as our knowledge goes, it is perfectly free from harm." I know of several cases in which extensive scarring or permanent alopecia has been the result of, and others in which the disease has not been cured by, x ray epilation—at the hands, indeed, of skilled operators.

I am, Sir, yours faithfully,
Henrietta street, W., May 17th, 1909. PHIN. S. ABRAHAM.

THE SPREAD OF TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—I have read with considerable interest Dr. J. G. Emanuel's address on the Spread of Tuberculosis published in THE LANCET of May 15th, p. 1369. Whilst agreeing with most of his arguments, there are two points upon which I should like his explanation. Whence does he derive his information for the following statement?—"The appearance of phthisis in places now used as health resorts, previously immune from the disease." He mentions certain places in the South of Europe where *it is alleged* such infection has occurred. It is of importance that no undue alarm should be caused by exaggerated statements as to the infectivity of pulmonary tuberculosis and that any *opinion in regard to the spread of the disease* should be fully supported by experience. Already serious inconvenience has been caused to the unfortunate sufferers from the disease by their exclusion from certain European resorts, and Dr. Emanuel's remark quoted above is likely to add to the feeling of nervousness already felt as regards the justification of allowing tuberculous individuals to mix with their fellow creatures at such resorts. As far as I am aware no such statistics as would support Dr. Emanuel's statement have yet been published: if they have I should be obliged if he would be good enough to give me the reference. The infectivity of pulmonary tuberculosis cannot be denied, but undue exaggeration of the fact is likely to lead to uncalled-for disaster to individuals.

Dr. Emanuel also remarks that the subject of his address was prompted by the knowledge of the attitude of insurance companies in reference to a family history of tuberculosis." He says: "As soon as an individual applies to insure his life, if there is any consumption in his family he is made to pay a high premium if he be not actually refused; whereas another applicant with a good family history is passed as a first-class life, though he may be daily exposed to infection either at home through his wife and children or at his daily work." This statement requires considerable modification. At some of the large insurance companies, when there is a family history of tuberculosis, before any addition is made to the premium full inquiries are made as regards the possibility of infection, and the physique of the applicant is also duly noted. In other words, the family history is not deemed sufficient cause for an increase unless the incidence of tuberculosis is very marked.

I am, Sir, yours faithfully,

F. J. WETHERED.

Harley-street, W., May 15th, 1909.

To the Editor of THE LANCET.

SIR,—No one dissents nowadays from the dogma that tuberculosis is an infective disease, but there must be many who are not prepared to accept Dr. J. G. Emanuel's conclusion that heredity is a negligible factor or to admit that his interpretation of the facts is correct. Let me draw attention *to the statement that there can be no sharp distinction* between susceptibility and immunity because 1 in 9·5 of all persons dies from tuberculosis. In the six families quoted by him, comprising some 55 persons, 14 died from tuberculosis and some 10 more were suffering from the disease; a probable death-rate of 1 in 2·3 in tuberculous families. In other tuberculous families of which one has knowledge, three out of six, five out of eight, three out of eight, and so on, died from phthisis, showing that the families selected by Dr. Emanuel are not exceptional. On that reckoning there must be a large number of families where there is no death from tuberculosis, or only an occasional and more or less accidental one, and consequently there may be a very sharp line of distinction between susceptibility and immunity.

In order to see clearly the part which heredity plays in this disease it is necessary to differentiate the two main types of tuberculosis. The infantile form is almost entirely alimentary; if we recognise, as we must, that meningitis and general tuberculosis are merely disseminations from a primary lesion we can reckon them in the death-tables with the predominant primary lesion at each epoch. We find, then, that alimentary tuberculosis accounts for 85 per cent. of the deaths during the first five years of life, descending in *mortality from the first to the fifth.* It may be that heredity plays little or no part here. The second form is adolescent and respiratory. It begins to reach a formidable figure about the fifteenth year when adolescence sets in; and it is to be noted that its ravages begin in girls earlier than in boys in accordance with the earlier onset of *adolescence.* Now the principal feature at this period is not increased opportunities of infection, but the development of inherited physical characters upon which depends the greater or less power to resist infection. Infection, which involves other considerations beyond a chance inhalation of tubercle bacilli, may occur then or at any time within the next 20 years or so, by [illegible] out, [illegible] noted [illegible] rease [illegible] live longer and increase the death-rate at a later age.

In adolescent tuberculosis, then, heredity assumes extreme importance; for the physical characters on which susceptibility rests admit of *development and strengthening* by suitable environment and training. Therefore the advice given by Dr. Emanuel that we should devote our attention to the paths of infection and neglect the predisposition of the individual, appears to me pernicious and detrimental to the individual. The association of inherited physical characters of a tuberculous parent with a proneness to tuberculosis in the offspring has hitherto been generally accepted; but if it were necessary to adduce proof of it no doubt many general practitioners have knowledge of families where for two, three, or even four generations some physical conformation has been associated with phthisis. I have myself met with one striking example extending over three generations, as well as many of parent and child. It is certainly to be hoped that while every effort is made to destroy the opportunities of infection, the mistake will not be made of holding individual predisposition too cheaply.

I am, Sir, yours faithfully,

DONALD F. SHEARER.

Putney, S.W., May 17th, 1909.

PROPOSED LEGISLATION IN REGARD TO THE ADMINISTRATION OF ANÆSTHETICS.

To the Editor of THE LANCET.

SIR,—Several letters have recently appeared not only in your columns but in the lay press relating to a proposed Bill for controlling the administration of anæsthetics. These letters present great divergencies of opinion on the question whether *future* registered dental practitioners should be regarded as fitted to assume the responsibilities of general anæsthesia. In deciding such a question the paramount consideration must be the safety of the patients—viz., the British public.

It is obvious, I think, that he who renders another person surgically unconscious with any anæsthetic so disturbs the vital functions that, for the time being, the life of that person is completely in his hands. The public may therefore reasonably expect that the administrator of a general anæsthetic for a dental operation shall have undergone such general training as will enable him not only to recognise and meet emergencies connected with the anæsthetic but those also which might occur from accidents in the course of the operation—*e.g.*, *slipping* of a tooth or any *other foreign* body (such as a blade of forceps or portion of a prop) into the respiratory passages. Is the general medical and surgical training of the dentist such as to fit him to assume these responsibilities and to meet such emergencies?

Personally I am inclined to think that we should be consulting the best interests of the public by placing dental patients in the hands of the medical profession whenever it is necessary to administer a general anæsthetic. By such a line of action the reprehensible and dangerous practice of a single individual simultaneously assuming the functions of anæsthetist and operator would practically cease to exist. Apart, however, from these considerations as to the safety of the public it would, I think, be good policy for the dental profession to support a Bill which, if passed, would undoubtedly greatly restrict unregistered dental practice and might, perhaps, pave the way towards the goal desired by that profession—viz., the prohibition of this form of practice.

Why should not the proposed Bill be modified so as to prohibit the use of dangerous local anæsthetics except by registered medical and registered dental practitioners?

Such a modification would still further limit unregistered dental practice and would, I venture to think, be acceptable to the medical and dental professions.

I am, Sir, yours faithfully,

WILLIAM HERN.

Stratford place, W.

THE QUESTION OF COMPULSORY INSURANCE AGAINST SICKNESS.

To the Editor of THE LANCET.

SIR,—That the present system of medical attendance in this country can no longer be regarded as satisfactory, and that a new departure is imminent, is abundantly clear from the Poor-law Commission report and from the Chancellor of the *Exchequer's speech on the Budget. The Poor-law Com*mission has produced a great amount of evidence to show that not only those in receipt of relief but the poorest of the labouring classes are suffering from the want of a properly organised system of medical attendance. The writers of the Minority Report have painted the picture in still more lurid colours. No attention, they say, is paid by the majority of medical officers under the Poor-law to sanitary surroundings, and practically nothing is done towards the prevention of disease. "In too many unions, it is clear, outdoor medical relief begins and ends with a bottle of medicine." The writers of the Minority Report are probably most intimately acquainted with medical practice in London, but so far as the country and provincial towns are concerned I can testify from long experience in practice in [illegible] there is much that is true. Nor can it in present circumstances be otherwise. The conditions of medical attendance are such [illegible] treatment and attention is practically [illegible] medical officers [illegible] as a rule, underpaid. The out-patient departments of hospitals are so crowded that but little attention can be given to each individual case. The patients whom the physician or surgeon sees are entire strangers to him. He can know practically nothing of their mode of life, their means of subsistence, or their sanitary surroundings, and can therefore do but little towards the prevention of disease. Nor is it possible for a medical man who charges *6d.* or less for advice and medicine to give much attention to individual patients if he is to live by his profession. In some out-lying districts matters are still worse, for there, it appears, about half the people die without even having seen a doctor or got the conventional bottle of medicine. Bad as our system of medical attendance is from the patients' point of view, it is still worse from that of medical men, and if things continue as at present the general practitioner who knows the lives of his patients must soon vanish; and I am old-fashioned enough to believe that if he does, or if his place is taken by mere officialdom, it will be a grievous loss to the community.

While practically all are agreed as to the unsatisfactoriness of our present conditions of medical attendance, there are probably only a few who, like myself, have long urged in season and out of season that the only remedy for the present state of matters lies in direct interference by the State. Various methods have been possible in the past, but since members of the Cabinet, Labour Members of Parliament, and others have been visiting Germany and taking an interest in continental methods it is evident that for some time at least the system of compulsory insurance against sickness, and this, of course, must include medical attendance, will hold the field. In the Majority Report of the Poor-law Commission it is expressly stated that it was only the want of time that prevented them going fully into this matter, and it is quite evident that the proposal to solve this question by the increase of provident dispensaries would be utterly futile if compulsory insurance were not adopted. Besides, now that the Chancellor of the Exchequer has spoken and declared in favour of compulsory insurance, and the present Government is evidently prepared to grapple with it, it can no longer be regarded as a mere foolish dream of faddists. And, certainly, no one who has studied the system of compulsory insurance against sickness in Germany and their methods of medical attendance inaugurated and now in force for a quarter of a century can fail to see how that country has benefited by it. After endless modifications through experience, the method in those towns and districts where it is well carried out is extremely simple. A deduction is made from wages to which are added contributions from the employer and the State. The particulars are entered in a pass-book. When the worker or one of his family takes ill the pass-book is taken to the doctor of his choice, who sees the patient at his surgery or, if necessary, at his house. If the patient has to be removed to the hospital or goes to a convalescent home, payment is made from the compulsory insurance fund, and this has been done without interference with the excellent work carried on by friendly societies. No one can deny that, compared with our methods in our country, this is vastly to the advantage of the patient. But what as to the doctors? One hears over and over again that any system of this sort should be vigorously opposed by medical men, as medical men are so poorly paid in Germany and are so much worse off than in this country. I do not believe it, and statements of this sort made in medical journals I have not found to be supported by an atom of proof. I defy anyone to produce any medical man in Germany who, though he may have many complaints, will not at once admit that he is vastly better off with this system of insurance than he would have been without. It would take too much space to go into particulars, but be it carefully noted that this system applies only to those whose income is less than £100, or in exceptional circumstances £150, a year, and that those earning more than this sum [illegible] country they so often do, obtain treatment [illegible] or gratuitously. The Chancellor of the Exchequer [illegible] that for settling the details of this [illegible] the heads of friendly societies. Medical [illegible] equally interested, [illegible] is should be, but I [illegible] our profession have [illegible] interested.

I am, Sir, yours faithfully,
J. H. KEAY.

Greenwich, May 10th, 1909.

THE LATE SIR WILLIAM GAIRDNER

To the Editor of THE LANCET.

SIR,—In response to the wishes of Lady Gairdner [illegible] family I have undertaken to edit the medical and [illegible] papers and articles of the late Sir William Tennant [illegible] and to preface the collection with a biography. In order to render the work as worthy as possible of the memory [illegible] late professor I am desirous of enlisting the sympathy and help of his friends. I venture, therefore, to request [illegible] your columns that anyone who has in his possession letters or other literary remains of Sir William Gairdner will be so kind as to communicate with me.

I am, Sir, yours faithfully,
G. A. GIBSON, M.D. Edin.

3, Drumsheugh-gardens, Edinburgh, May 12th, 1909.

THE BUDGET AND MEDICAL PRACTITIONERS.

To the Editor of THE LANCET.

SIR,—Is it not beneath the dignity of the profession to take the ground which many have, and go cap in hand [illegible] ask the Chancellor of the Exchequer to grant [illegible] in the petrol tax, and to urge each member of the profession to seek the good offices of his Member of Parliament to assist us in the matter? It seems to me not only degrading, but [illegible] that we have no claim to any special abatement. We should face the expenses of our own profession like every [illegible] citizen and should be above asking or accepting doles; [illegible] we should have the manliness to fight for our just rights.

It is not in legitimate taxes where the shoe pinches us as a profession. But we do feel, and resent, the injustice we suffer in being coerced, under penalty, to give our work to the State as no other members of the nation are ever [illegible] to do. It is not just to demand from us certificates of death gratis; they are required solely [illegible] unfair to constrain us to notify [illegible] It should not be obligatory on resident or visiting [illegible] of the staffs of large or small hospitals to make post [illegible] examinations [illegible] on accidents [illegible] ment. Surely [illegible] burdened by [illegible] few of the ins[illegible] and it is in such cases where we suffer in dignity as [illegible] financially.

We do not wish, and ought not to seek, concessions; we ought, one and all, to contend for our rights as members of a noble profession and as citizens of this great empire. If we honoured ourselves more we should receive [illegible] honour in return. Let us cease asking for alms for the few and claim what is our birthright for all. If we [illegible] to accept concessions in taxation for those of us who happen to be sufficiently well off to be able to keep cars, what will the answer be when we claim as our right just payment [illegible] work done for the State?

I am, Sir, yours faithfully,
CLEMENT DUKES.

Rugby, May 15th, 190[illegible].

BOARDS OF GUARDIANS AND PUBLIC VACCINATORS.

To the Editor of [illegible]

SIR,—There is a slight inac[illegible] p. 1407 of this week's issue of THE [illegible] of Guardians and Public Vaccinators." [illegible] proposition is quite correct and you rightly [illegible] inequity; but it is not true to say that if a public resigns his vaccination the guardians can dismiss him from his Poor-law office, for this is not the case. But as it is nearly always the latter office that is underpaid it is mostly the district medical officer and not the public vaccinator who is forced to resign.

Apart from this slight inaccuracy, our service is greatly indebted to you for drawing public attention to a great abuse of the power of the guardians, certainly not contemplated by the legislation, and a great grievance both to Poor-law medical officers and to the medical profession generally.

I am, Sir, yours faithfully,
M. GREENWOOD,
Honorary Secretary, Poor-law Medical Officers' Association of England and Wales.
London, E C., May 15th, 1909.

EPSOM SALTS AS A POISON.

To the Editor of THE LANCET.

SIR,—With reference to my article in THE LANCET of April 24th, p. 1174, on Epsom Salts as a Poison, I have had my attention drawn by Dr. W. Sang to the fact that Cases 4 and 6 (Sang's case) present such points of similarity in respect of time, locality, sex, dose, and final result as to suggest the possibility that the two cases may be one and the same.

This opinion I am now in a position to verify. For although my references bear different dates I am satisfied that the scanty details of Case 4 in the *British Medical Journal* and the fuller report of Case 6 in a later issue of THE LANCET are concerned with one and the same subject, the former appearing as a "news" item, while the latter appeared as an original article.

I shall be glad if you will kindly publish this correction so that future references may not be vitiated.

I am, Sir, yours faithfully,
Brighton, May 15th, 1909. CHARLES FRASER.

BRISTOL AND THE WESTERN COUNTIES.

The University in Being.

NEWS reached Bristol on Monday evening, May 17th, to the effect that the University Charter had received the approval of the Privy Council and now only waits for the affixing of His Majesty's Sign Manual. Many churches rang their bells and ran up flags in recognition of the great importance of this event. It is 35 years since a public meeting was held to inaugurate a University College in Bristol, at which the late Archbishop Temple (then Bishop of Exeter) was one of the speakers. Two of the Oxford colleges, Balliol and New, gave substantial support to the scheme on certain general conditions, and in October, 1876, the College was actually opened in temporary premises. The Bristol Medical School, *which had already been at* work many years on an independent basis, [illegible] as the faculty of medicin [illegible] were opened in 1880, and [illegible] stantial additions have been made to these, the last being in 1904. These provide a home for faculties of arts, science, engineering, and medicine. There is no doubt that those who were most intimately concerned in promoting the welfare of the College saw in it the nucleus of a university, and, obedient to this vision, they have sustained the policy of expansion throughout. The support afforded by the public has not always been what it might, with a few brilliant and generous exceptions; but since the year 1899, when the University College Colston Society was founded, the public attention and interest have been increasingly concentrated upon the University scheme. This society has collected over £5000 for the University, and has enlisted the support of many eminent men who have spoken at the annual dinners. It was at the 1908 dinner that Mr. Henry Overton Wills's promise of £100,000 was made public. Since that time the development of the scheme has advanced rapidly. His Majesty's visit in July last was made the opportunity for presenting a petition relating to the charter, new buildings have been acquired, and funds collected, till the total value of University property has surpassed the minimum (£250,000) at which a charter can be granted; the city council has devoted an annual rate of 1*d*. in the £ towards the income of the University; and a Parliamentary Bill transferring the property and liabilities of University College, Bristol, to the University of Bristol has been approved by the governors of the former. Arrangements have also been made for the inclusion of the Merchant Venturers' Technical College in the University as a faculty of engineering. There are two family names which will always be honourably remembered in connexion with the foundation of the University of Bristol—those of Wills and Fry. Their support is not to be reckoned in pounds, shillings, and pence merely, though in this respect their contributions have been lavish; there is also a great debt of gratitude owing to them for the interest, personal influence, and capacity for organisation which have been freely devoted to the project which has now been crowned by the Royal approval. I must defer the consideration of the terms of the charter to a later communication.

Other University Intelligence.

Two appointments that are very gratifying to the Bristol Medical School have recently been made. The Bradshaw lecturer of the Royal College of Surgeons of England for 1910 is Mr. F. Richardson Cross; and Dr. J. M. Fortescue-Brickdale, the director of the Public Health Laboratory, has been made lecturer on Pharmacology to the University of Oxford.—At a recent meeting of the Workers' Educational Association, Mr. G. H. Leonard, professor of history at University College, who was in the chair, said that the working-classes were to have more representatives in the court of the *University of Bristol than in any other university court in* the kingdom. There were to be eight in all, the president and two members of the Trades Council, two members of the Friendly Societies' Council, two members of the Coöperative Society, and one member of the Workers' Educational Association. He also announced the provision at University College, by a lady who did not wish her name published, of two small scholarships for working people.

The Bristol City and County Asylum, Fishponds.

The medical superintendent of the Bristol County Asylum (Dr. J. V. Blackford) reports that during 1908 the admissions numbered 247 (103 men and 144 women). The percentage of recoveries on the admissions, excluding transfer cases, was 42·42, and compared favourably with previous years; 84 patients were discharged as recovered. The number of deaths during the year was 140—viz., 74 males and 66 females —the death-rate on the average number of resident patients being 15·09. Post-mortem examinations were made in 123 cases, *being over 87 per cent. on the total deaths, all of* which were due to natural causes. The highest number of patients resident at one time during the year was 915. The new wards for male patients are to be opened on May 25th.

An Interesting Compensation Case at Exeter.

At Exeter county court last week, before his honour Judge Lush Wilson, K.C., a claim for compensation was made by a *farm labourer against his employer, a local farmer. The applicant* was asked to clean out a tannery pit. The liquor to be removed from such pit consisted of the acid and bloody fluid which drained off the skins, the acid having been added to clean the skins. The acid percolated through the labourer's boots, caused vesicles to form on his feet, and eventually blood poisoning followed. His honour said the question he had to decide was that the blood poisoning was caused by accident arising out of his employment, and gave judgment for the applicant.

A Poor-law Medical Officer's Salary.

Some time ago the Local Government Board informed the Falmouth board of guardians that the salary of £20 per annum allowed to Mr. *Dudley R. Harris as medical officer to* the workhouse was inadequate, and the late inspector (Mr. Preston Thomas) spoke *very strongly about the matter.* At the last meeting of the guardians a letter was read from the Local Government Board asking the guardians to reconsider the salary of their workhouse medical officer. After some discussion it was resolved to refer the subject to the house committee. It is to be hoped that the guardians will follow the advice given them and award Mr. Harris an adequate salary.

A Proposed Memorial to Dr. Hugh Montgomerie of Penzance

It is proposed to endow a bed in the West Cornwall Infirmary, Penzance, to the memory of the late Dr. Hugh Montgomerie. Several subscriptions have been received including £200 from Mr. and Mrs. R. Bolitho. It is probable that the Lord Mayor of London, when he visits Penzance next month, will dedicate the bed, and the Lady Mayoress will be asked to receive purses on its behalf. Dr. Montgomerie was for some years honorary physician to the West Cornwall Infirmary, and his father and grandfather had also been members of the honorary staff to the institution.

The Local Government Board and the Torrington Board of Guardians.

At a meeting of the Torrington board of guardians held recently a letter was read from the Local Government Board taking exception to the appointment of the medical officer for the Dolton district being for a definite term, as proposed by the guardians, as the usual custom was for such appointments to be permanent. After a considerable discussion it was resolved to appeal to Mr. G. Lambert, M.P., to interview the President of the Local Government Board on the matter.

A Proposed Isolation Hospital for Tavistock.

At the last meeting of the Tavistock (Devon) urban council a letter was read from the Duke of Bedford, stating that if the Tavistock rural and urban councils decide to build a joint isolation hospital he would contribute half the cost if under £2000, or £1000 if the cost be over £2000. After some discussion a committee was appointed to draw up a scheme and report.

May 18th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

LAST Saturday it became known that the King and Queen would visit Birmingham on July 7th to open the new buildings at Bournbrook. Thus the long-cherished wish of the city is to be realised and the preparations, which were commenced with hope but without knowledge, will now be pushed rapidly forward. Several of the departments in the new buildings, including those of engineering, metallurgy, and mining, are finished and have been in use. The departments of chemistry and physics, the Harding library, and the tower are well advanced towards completion and the grounds are beginning to assume a pleasant and well-looked-after aspect. Visitors who have not seen the new part of the University will be surprised at the stateliness and beauty of the design and the magnificent scale upon which it is being carried out. The whole scheme will not be completed in this generation unless many bountiful donations are received, but the grandeur of the conception on which it is based is even now very evident. The magnificence as well as the utility of their new possession has not yet been fully grasped by the city as a whole, but the time will come when it will be universally realised and the city will look with pride upon what will be one of the most potent factors in its future history.

The Milk-supply and Tuberculosis.

At the provincial sessional meeting of the Royal Sanitary Institute held in the Medical Theatre of the University last week Mr. J. Malcolm initiated a discussion upon Tuberculosis and Milk-supply by an interesting paper dealing chiefly with remedial measures. It appears from Mr. Malcolm's statements and from the discussion which followed the expression of his opinions that the main obstacle to rapid improvement of the dairy cattle is expense. It was admitted that whilst testing and subsequent segregation of reacting cattle will eventually free the country from a formidable source of infection, still that process is relatively slow, and to make it thoroughly effective it must be combined with improvement of the buildings in which the animals are housed. It was urged that in the long run the most economical method was the destruction of the infected cattle, for by that means the best prices would be secured for the animals and the farm would most rapidly become clean and more fully remunerative, especially if at the same time the cowsheds were rendered more healthy. There was difference of opinion, however, as to the means by which the cowsheds could be most economically and effectively adapted to their purpose, some of the speakers inclining to the provision of a greater amount of cubic space and others being inclined to rely upon improved ventilation. The provision or non-provision of compensation for the destroyed animals is obviously one which will greatly influence the rapidity of the steps taken to secure improvement, and Sir Richard Cooper stated his conviction that if the farmers were prepared to deal with the subject in a reasonable way and approached the Board of Agriculture with reasonable proposals they would be liberally met and compensation would be granted. If this conviction is well founded farmers should be strongly urged to take quick action, for the welfare of many thousands of children depends upon the rapidity with which the present conditions can be replaced by others of a more satisfactory character. Steps have already been taken by our health committee for the supply of pure milk to public institutions. 11 farms are now being dealt with and four are already completely free from the disease.

Suggested Diploma for Veterinary Surgeons.

It has been suggested that the University should grant diplomas to properly qualified veterinary surgeons on lines somewhat similar to those which have been adopted by some other provincial universities. The matter is still under the consideration of the University authorities and it has also been referred to the council of the Midland Counties Veterinary Medical Association. There is little doubt that, if it seems desirable to take action, the University will be prepared to take the necessary steps and to provide a proper curriculum.

The General Hospital.

At a recent meeting of the board of management the Earl of Plymouth was elected President of the General Hospital, an appointment which carries with it the presidency of the Triennial Musical Festival which takes place next October. At the same meeting it was announced that Mrs. Rickards had decided to give to the hospital £1200 for the purpose of dedicating a bed to the memory of the late Dr. Edwin Rickards, who was connected with, and gave very valuable services to, the hospital for a period of 36 years.

The Decline of the Measles Epidemic.

Between March 9th and 16th last we were at or near the highest point of the measles epidemic, from which the city and district have suffered severely, and the measles death-rate for the week totalled 44. From that period onward the decline commenced, and by April 6th the deaths from measles had fallen to 30 for the week. By April 20th the deaths had fall to 14 for the week. They were slightly more numerous during the next three weeks, but last week the decrease was rapid and only five deaths from measles were registered. We may congratulate ourselves, therefore, that we have passed through the worst of the epidemic and have entered on the comparatively free period which regularly follows the epidemic attacks.

May 18th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Electricity Out of Control.

IT is perhaps well that our boastings as to applied science, such as the harnessing of the giant electricity for our own use, should now and then be a little disturbed, if only to remind us that these powers are as dangerous as they are useful. A series of explosions which took place on May 8th show that our control is still imperfect. The tramway wires at the junction of two streets in Hulme fused and burst into flames, and a moment later a cable-box at the foot of one of the standards exploded and blue flames shot out from the standard. Without warning another violent explosion occurred—a section-box bursting and causing a panic amongst the crowd that had gathered, and the flames from this box threatened to spread to adjacent buildings. It was found almost immediately that there was an outbreak in a chapel in Jackson-street and an outbreak at the Bridgewater Canal offices. Happily there were no personal injuries or loss of life. More or less similar occurrences happen from time to time in Manchester, and no doubt in other large towns, showing that the necessity still exists for perfecting our control over the powers of this invaluable agent.

Overcrowding.

Under the direction of Dr. J. Niven a census has been recently taken of dwellings sublet in the city. In one district, out of 1112 inhabited houses, 205 were sublet into 655 tenements, 439 being of one room only. Another district showed 1966 houses with 249 sublet, while the death-rate closely follows the density of the population. In Ancoats and Hulme, where the population is over 100 to the acre, the death-rate is more than twice as high as at Wittington, Moston, and Clayton, where the population averages about 15 persons to the acre.

Milk.

Councillor Hailwood of Salford, speaking a few days ago as President of the National Federation of Dairymen and Cowkeepers' Association, spoke, as was natural, in praise of milk as the "cheapest and most nourishing" food that went into the house, and said very truly that if children had more milk in place of tea and coffee a great improvement would be seen in their health in a very short time. He gave some interesting figures as to the daily consumption of milk in large cities. Boston, U.S.A., heads the list with 20 ounces the daily consumption per head of the population. In Edinburgh and Glasgow the consumption is only half as much. In Liverpool and Sheffield it was seven ounces, but in Manchester and Salford only four ounces.—On Saturday, May 8th, a meeting was held at Chester of the North-Western centre of the Sanitary Inspectors' Association, when a paper was read on Municipalities and the Milk Problem, in which it was suggested that cowkeepers and milk-sellers should be licensed annually by local authorities. In the discussion that followed it was said that they could not expect a pure, wholesome, unadulterated milk-supply unless consumers were prepared to pay the cost, and one would be afraid that with greater stringency as to the provisions for securing a pure milk-supply the increased cost would tend to restrict consumption, especially in the poorer households. It would be safe to say that on the whole there are more care and cleanliness with regard to milking and the after-care of milk than was formerly the case, but we seldom hear of ill-effects from the taking of milk except in the cases where it has served as the carrier of infectious diseases, such as typhoid or scarlet fever. At the same time, the following true story shows how primitive in some cases the ideas of cleanliness are. A lady who employed her servant in milking her one cow, asked her one day if she had washed her hands before milking. The girl answered, "Oh no, I always wash them in the milk." Dr. J. R. Currie, the assistant medical officer of health of Chester, pointed out that the calves of tuberculous cattle were not affected with the disease, and by being fed on pure milk might be kept free from it.

May 18th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Treasury Committee and the Scottish Universities.

THIS committee, which the Government appointed some time ago to inquire into the needs of the Scottish Universities, has been in Edinburgh lately. The committee is presided over by Lord Elgin. The members visited the various medical teaching centres outside the University as well as the various departments in the University. Evidence has been taken from the Principal and others. University teaching, extra-mural teaching, and the teaching of women have all been inquired into. It is hoped that the result of the inquiries may be an increased grant to Edinburgh, for the University is much in need of money.

Appointment of Assistant Physician to Edinburgh Royal Infirmary.

The managers of the Edinburgh Royal Infirmary have appointed Dr. Edwin Matthew an assistant physician to the infirmary. Dr. Matthew is a graduate in arts of Aberdeen, and graduated in medicine at Edinburgh in 1897. He has for a number of years been an assistant physician to Leith Hospital. There were four other applicants.

The Illness of two Edinburgh Professors.

I regret to say that Professor J. Chiene has required to have his leave of absence prolonged on account of health. Professor D. J. Cunningham, who had gone to Egypt for rest and to regain strength, has returned without having received such benefit as his friends had hoped.

Edinburgh Post-Graduate Vacation Course in Medicine.

The syllabus of this course [illegible] all the necessary information, [illegible] may make up their time-table [illegible] will extend from Monday, August 30th, to Saturday, Sept. 25th, and will comprise (1) a general course, the composite fee for which will be 5 guineas for the four weeks, or 3 guineas for either the first or second fortnight; and (2) a surgical course, which will include classes on operative surgery, surgical anatomy, surgical pathology, and x rays applied to surgery. These classes will be exclusively reserved for those attending the surgical course, the composite fee for which will be 10 guineas. 3. Special classes on (*a*) bacteriology; (*b*) the blood; (*c*) the ear and throat; (*d*) gynæcology; (*e*) histological methods; (*f*) ophthalmology; (*g*) errors of refraction; and (*h*) x rays, the fee for each being 1 guinea. Each day throughout the course a special lecture will be delivered at five o'clock upon some subject of general medical or surgical interest. The University union will allow graduates to become temporary members for one month on payment of a fee of 5*s.* In the general course the subjects of medical anatomy, diseases of children, medical inspection of school-children, dermatology, diseases of the eye, infant feeding, infectious diseases, neurology, pathological anatomy, and tropical and venereal diseases find a place. In the past these post-graduate courses have been remarkably successful, and it is to be hoped that an equal if not greater success will follow this course.

Montrose Asylums Board and Parish Council Representation.

An important conference took place at Montrose on May 12th between members of the General Board of Lunacy and the managers of the Sunnyside Asylum as to the proposed change in the charter so as to admit popular representation by parish councils on the asylum management. Dr. J. Macpherson, Commissioner in Lunacy, said that the present board was composed of members drawn exclusively from the town of Montrose and the immediate neighbourhood, so that the parish councils of Forfarshire were compelled by law to send their patients to an institution in the management of which neither they nor any other representative body within the county had any direct voice. He thought that the present arrangement was a most unfortunate one, and that it ought to be terminated as speedily as possible. He outlined a scheme indicating an asylum committee, consisting in all of from 10 to 12 members. After a lengthy discussion the board of managers decided to meet specially to consider the question.

Aberdeen Royal Infirmary: Resignation of Dr. Angus Fraser.

At a meeting of the directors of the Aberdeen Royal Infirmary, held on May 12th, a letter was submitted from Dr. Angus Fraser intimating his resignation as an infirmary physician. The board resolved to record its high appreciation of the invaluable service rendered by Dr. Fraser to the hospital, and through it to the sick poor of the city of Aberdeen and large surrounding district, during the long period of 38 years in which he had occupied the position of a physician on the staff of the infirmary; its sense of the very high honour it had been to the infirmary to have had for so long on the roll of its officials the name of one so distinguished in his profession; and its grateful recognition of the other many and varied ways in which Dr. Fraser had, by his sagacious counsel and his unsurpassed knowledge of the history and working of the institution, contributed to its welfare and success. It was resolved to request Dr. Fraser's permission to continue his name on the staff of the infirmary as a consulting physician.

Sidlaw Sanatorium.

The executive of the Sidlaw Sanatorium at a meeting on May 11th acceded to a request by the Dundee town council to have the agreement for municipalisation cancelled on the understanding that the town council pay the expenses incurred in connexion with the negotiations. Mr. F. B. Sharp, the chairman, in a letter, expressed the opinion that the town council was under a moral obligation to make good to the sanatorium the permanent [illegible] sustained in consequence of its action in [illegible] for the acquisition of the sanatorium by the town and then asking them to cancel an honourable agreement. He also added that he was willing to make good any deficit (not exceeding £300) which might arise on the working of the sanatorium on its present lines from May 1st to Dec. 31st of this year.

Presentation to an Inverness Practitioner.

On May 11th Dr. G. W. England Kerr of Inverness was, on the occasion of his wedding, presented with a beautiful motor car and with a purse of sovereigns, while his wife also received a gift. Mr. James Ross, rector of the Mackenzie School, made the presentations on behalf of the subscribers, who numbered over 1800.

Keith Town Council and Pulmonary Tuberculosis.

At a meeting of the Keith town council, held on May 10th, it was decided to include pulmonary tuberculosis among notifiable diseases.

May 18th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Mortality in Irish Towns.

THE second week of the present month showed a more favourable death-rate record than any of its predecessors for a number of years. The rate fell from 23 per 1000 of the population in the previous week to 18·75. The average of the four preceding weeks had been 23·5. The highest death-rate of the second week of May which occurred in Ireland was that of Kilkenny, which reached 39·3. No deaths occurred in Clonmel, another favourable contrast from the 36 per 1000 of the week preceding. In three other town districts only was the rate below 10 per 1000: Drogheda (8·2), Sligo (4·75), and Galway (4). The death-rate of Queenstown reached 33. The total number of deaths which occurred in Dublin was 133, the number of births being 301. During the 18 weeks which ended with the second week of this month the average death-rate of Dublin was 26·5 per 1000—being 1·5 below the average for the corresponding periods of the past ten years. The deaths from whooping-cough fell to four, as against 13 of the previous week. Those from tuberculous disease fell from 33 to 29, which included 23 from pulmonary consumption. There were no fresh cases of whooping-cough reported in the city area, but 14 cases were reported from the Pembroke township. Four cases of scarlet fever occurred in Rathmines. There were seven cases of diphtheria reported in the city and one in Rathmines; the other townships remained free.

The Medical Officer of Health of Belfast.

In reply to a letter of the public health committee asking the Local Government Board to reconsider its decision regarding the proposal of the Belfast Corporation to increase the salary of the medical officer of health, the Local Government Board has written that it was unable to vary its decision and that it saw no reason for departing in this case from its usual practice of requiring a period of five years' service before sanctioning increase in an officer's salary. The health committee has expressed its regret at this decision which is final.

Ballykelly Dispensary.

Dr. J. R. Ross has just been obliged, owing to the state of his health and his age (69), to tender his resignation of the office of medical officer of Ballykelly Dispensary, a position which he has held for 42 years. At a meeting of the Limavady board of guardians held on May 17th the resignation was accepted and a resolution was unanimously passed acknowledging Dr. Ross's faithful services, particularly to the poor.

The Queen's University Commission.

This Commission began further sittings on May 17th at Queen's College, Belfast. The selection of the new professors and lecturers was considered; and deputations were received from the Technical Institute in reference to coördinating university and technical education, and from the other institutions in regard to recognition as a teaching institution.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Isotonic Sugar Solutions for Injection.

AT a recent meeting of the French Society of Military Medicine M. J. Labougle and M. Boutin communicated a paper in which they called to mind the undesirable results which sometimes occur from injections of saline solutions, even when they were isotonic, and they proposed the replacement of the sodium chloride by sugar. A solution composed of 10·30 grammes of sugar in distilled water is, they state, perfectly isotonic, is cryoscopic in the same degree as the blood serum, is non-toxic, and has been employed with the greatest success in various cases of serious illness, such as typhoid fever, malaria, and septicæmia. These sugar injections have the same good effects as those of artificial serum without giving rise to the disagreeable effects which the latter sometimes produce, and they can be used without risk even in patients suffering from acute albuminuria. Moreover, they produce abundant diuresis. The only contra-indication to their use is diabetes.

Ophthalmia in the Newly Born.

At a meeting of the Academy of Medicine held on May 4th M. Motais read a paper in which he advocated the use of protargol instead of nitrate of silver in the treatment of ophthalmia of the new-born infant. The eyelids are everted and gently washed with a solution of potassium permanganate of a strength of 1 in 400. Then two drops of a solution of protargol, one gramme to five grammes of distilled water, are dropped into the eye every three hours, day and night, for two or three days, until the secretion becomes less in quantity and of thin consistency. When this happens the instillation is only made every six hours. After five or six days of this treatment there is hardly any secretion and the swelling of the lids has practically disappeared. The treatment is continued with a solution of half the strength until complete cure is obtained. If ulceration of the cornea has commenced before the treatment is begun the protargol arrests the destructive process, and cicatrisation of the ulcer commences almost at once. Midwives are at present authorised to use preventive treatment by instilling into the eyes of a new-born child a solution of nitrate of silver of a strength of 2 per cent., and it is to be feared that as they have this solution at their disposal they will continue to use it. M. Motais considers that it would be more prudent to allow them to use nothing but a one in five solution of protargol, which is quite harmless although very active.

The Prevention of Blindness in Workers.

At the same meeting of the same society M. Motais discussed a most interesting and important question—namely, the measures to be taken for preserving the sight in workers who by their tasks are exposed to the risk of losing it He said that great importance was rightly attached to ocular hygiene in schools, but that no one took any heed of ocular hygiene in workshops, offices, and shops. The children in secondary schools throughout France numbered about 250,000. The number of workers of both sexes, such as dressmakers and embroiderers especially, and in other trades, those who are exposed to dust, to either too intense or not enough light, to injuries by pieces of steel, or stone, or coal, exceeds 3,000,000. Every year thousands of dressmakers, clerks, cashiers, and accountants lose their sight, not so much from excess of work as from defective lighting and a deplorably faulty position during their work. Each year, too, thousands of workers become blind from irritating dust, fragments of iron, coal, glass, wood, or stone shot into the cornea, or from exposure to intense lights. To remedy this state of things M. Motais proposed the appointment of an inspector of factories who should look after the cleanliness of the windows, which are too often encumbered with dust or spiders' webs or overshadowed by trees. Arrangements for day lighting should be based on those at present in use in schools; for artificial lighting a special committee should be appointed. The use of protective spectacles should be made obligatory on all workers whose eyes are exposed to the possible impact of foreign bodies, and advice should be given to workers as to the importance of there being good light for their work.

Sero-therapy in Diphtheritic Paralysis.

At a meeting of the Hospitals Medical Society held on April 30th M. Mery, M. Weill-Hallé, and M. Parturier recommended the following method of administration of anti-diphtheritic serum for the prevention and cure of diphtheritic paralysis. The serum must be injected subcuta
by day both during and after the affection of
without waiting for the first manifestations of
Big doses must be used, from 40 to 60 cubic cei
day during the acute period, and after this from 10 to 20 cubic centimetres every two days. Also, according to M. Hutinel's advice, 10 centigrammes of powdered suprarenal body must be given every day. M. Netter has also used large doses of serum together with adrenalin. The *combination of these two therapeutic measures will cure a* certain number of severe diphtherias without complications. But as *grave cases of diphtheria do not always declare them*selves as such at the beginning of the disease the intensive treatment should be begun and continued in every case of diphtheria. The large doses of serum injected do not *appear to bring about any anaphylaxis or any toxic effects,* and M. Sicard stated that in one case of diphtheritic paralysis he had injected over 600 cubic centimetres of serum without any ill-effect.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

A Novelty in Open-air Treatment.

ON *the recommendation of several medical men in Vienna* the municipality last year opened an institution called here by the popular name of "Gauschäufel." It is simply an open-air sanatorium for healthy persons. The old idea that sunlight, air, and water are the main restoratives at our disposal was long ago taken up by a non-medical philanthropist, *who opened an establishment of the most primitive* kind on the banks of the Danube on the outskirts of Vienna. The results obtained by him have prompted the municipality to enlarge the establishment and conduct it on modern principles. An immense area covered with fine sand, deposited from the Danube, which used to flow there in ancient times, a long river bank with shallow, rapidly-flowing, cold water, and the absence of any shade-giving trees are the three principal health-giving factors relied on. Special care has been taken to enable schools to make use of the facilities offered there; 4000 persons can *undress at the same time, and free tickets* have been granted to schools and workshops, so that on some days last summer 10,000 persons were seen there, going about in the open air nearly naked. It must be admitted that the institution has done much to convince the lower classes of the good influence of a natural mode of life. No less than 200,000 persons have availed themselves of the opportunity offered them and for this year an increased area has been thrown open for the "air cure." There is a special medical attendant present, for cases of sunstroke have been noticed now and then, but, generally speaking, no serious mishap has occurred. As the inhabitants of Vienna, unlike those of London, have no sea coast within easy reach, this substitute has been welcomed by the population.

The Prevention of Venereal Disease among Students.

The increase of venereal disease amongst the better classes of the population, as well as the fact that young students fresh from school or country are very liable to succumb to sexual temptation, has prompted the senates of the universities not *only* in Austria but also in *Germany* to issue a printed warning to all students on matriculation, cautioning them against the dangers of venereal disease. In this leaflet the widely-diffused idea that sexual intercourse is absolutely necessary for the developing body is refuted, and the antiquated notion that "a little gonorrhœa" is nothing to be ashamed of is shown to be a serious and dangerous fallacy. *The students are reminded that such superstitions result in* terrible suffering on the part of innocent wives infected by their husbands, for gonorrhœa may completely undermine a woman's health, causing sterility and domestic unhappiness. It is added that in more than 50 per cent. of sterile marriages the first link in the chain of events has been gonorrhœa contracted by the husband. After recommending an immediate visit to a competent practitioner when once disease has been acquired and *cautioning against* secret remedies and quacks who make great promises, the leaflet goes on to say that sexual intercourse whilst a man is
It is signed by
Gruber, Dr. von
ppe, Dr. Neisser,
*ts to obtain com*petent help and advice in cases of disease special friendly societies (*Krankencassen*) have been formed for students of all universities and all branches in Austria The medical men attached to them have mostly been at one time members of a *Cassa* themselves, and the students in this way have at a very *small cost sufficient medical care and attention. It must be* mentioned that in this country numerous students come from poor families, so that the expense of treatment would be a very heavy burden to them but for these *Krankencassen.*

Horse Serum in the Treatment of Hæmophilia.

At a recent meeting of the Gesellschaft der Aerzte Dr. Mautner showed a boy, four and a half years old, who was suffering from hæmophilia and had once already been in hospital for dangerous hæmorrhage which was controlled with difficulty. This time the child was admitted in a nearly moribund condition, three days after the extraction of a lower molar tooth. He had been losing blood continually and the styptics applied locally were absolutely useless. Dr. Mautner thereupon injected 20 cubic centimetres of normal horse serum, acting on a suggestion made by Dr. Wirth and mentioned by me in THE LANCET of Feb. 13th, p. 508. *After* a few minutes the oozing became less and the bleeding soon stopped but reappeared the next day. Another injection of the same strength had a permanent effect. Whilst a blood count on admission showed only 1,700,000 erythrocytes per cubic millimetre their number rose to 2,700,000 five *days after the first injection and the general condition* of the patient improved rapidly. A remarkable feature of this case was an atypical serum disease appearing 28 days after injection, manifesting itself by a rise of temperature, swelling of the glands, pain in the joints, and leucopenia (4000 leucocytes per cubic millimetre). There also appeared at the same time a general erythema of the nature of erythema multiforme. A similar belated occurrence of a serum exanthem has been noticed several times in very debilitated persons. A point worth mentioning was the fact that the experiments on anaphylaxis showed that in addition to other changes the injection of serum caused also a loss of coagulability of the blood after two or three weeks. This, *however, was only in certain animals* which had received large amounts of serum intravenously, and especially in dogs. In human patients the amount of serum used was relatively much smaller and its absorption was much slower, otherwise there might be reason to fear that hæmophilic patients treated with horse serum would be in great danger if fresh bleeding should occur from 20 to 25 days after the injection. *That this did not happen has been* proved already.

May 17th.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

Public Executions.

MARTIAL law and court-martial have commenced the work of retribution with a stern and resolute hand. The instigators and the
soldiers and officers, civilians an
executed on open places of the
crowded and exposed, such as the Stamboul end of the Galata bridge, the wide space near Saint-Sophia, and the thoroughfare of the mosque of Sultan Bayezid. The executed men were exposed on their gibbets to the crowds for several hours, and with *feverish eagerness* great masses of people streamed out to see them suffer. The scenes were repulsive in the highest degree. A female patient of mine who saw the hangings was so affected by the horrible sight that she is bedridden at present in a febrile delirious condition and probably many more share her punishment for their morbid curiosity.

The Massacres at Adana.

The massacres at Adana and other places in the interior of Asia Minor have been, judging from the latest reports received at the American Bible House in Stamboul, of a most extensive and dreadful character. The Armenian Committee "Dashnaksutiun," which organised in Constantinople a very efficient medical staff to attend to the wounded in different hospitals of the city, has now sent to Adana a medical mission for the same purpose, consisting of three doctors, four assistants, and three nurses. The American missions have suffered greatly from the last reactionary disturbances in the interior. Several missionaries, medical and others, have been massacred and their houses destroyed by fire. The Government is sending a sufficient number of regiments to put an end to the reckless doings of the reactionaries and to punish the perpetrators. It seems that the latest massacres at Erzerum have been just as extensive and terrible as at Adana. According to the official report of Mustafa Sihni Pasha, the Vali (Governor) of Adana estimates that in the town itself, 345 Mahomedans were killed and 200 wounded. Among the Armenians the number of wounded amounted to 250 and of killed to 525. In the surroundings of the city 625 Moslems were killed and 40 wounded. The number of killed Armenians there was 250 and of wounded 30. According to the same official statement, in the whole vilayet of Adana 1924 Mahomedans and 1455 Armenians have been killed, and 533 of the former and 382 of the latter wounded. Out of a total of 250,000 people inhabiting the vilayet only 48,000 are Armenians. The court-martial has determined to verify thoroughly these statements of the Vali.

The New Sultan.

The new Padishah Mehmed V. was girt with the sword of Osman on the 10th of this month in the sacred mosque of Eyoub on the right shores of the Golden Horn, and thereby became the true and real "Shadow of Allah on Earth." The ceremony went off quite smoothly in splendid weather and with great Oriental pomp and splendour. The new Sultan seems to have become a very popular personality with his people, who admire his simplicity of manner and great readiness to mix among the population of the metropolis in an unrestrained manner. The Sultan has appointed a Greek doctor, Evlambios Effendi, to be his body-physician.

Some Statistics of Tuberculosis in Children.

In a clinical study on tuberculosis of children in Constantinople Dr. J. B. Violi gives some interesting statistics of his "Hôpital International des Enfants," of which he is the originator and director. From July 5th, 1895, till Dec. 31st, 1908, 39,749 sick children received medical and surgical treatment in this institution. Of this number, 475 were entered as suffering from tuberculosis of various forms. 175 had tuberculous peritonitis. In 25 of these cases Dr. Violi traced the origin of the disease to a contagion from father, mother, or some other person in the patient's immediate surroundings. The same observation was made in 22 cases out of 185 children who were afflicted with either tuberculous osteitis or periostitis; in 19 cases out of 69 of tuberculous meningitis; in three out of 25 with tuberculous glands; and in 11 out of 23 cases of pulmonary tuberculosis. Dr. Violi says that in view of these figures he should consider that 5 per cent. of the tuberculous patients in his hospital had the disease transmitted to them by persons with whom they lived in close contact. The following sequence of cases which occurred in Dr. Violi's private practice is of special interest in the same connexion. In July, 1906, he was called to attend, in a Turkish family, a girl, aged 13 years, who was suffering from pulmonary tuberculosis and who took care of her sister 18 months old. The advice of the medical man to keep the two children separate was not carried out. Three months later the babe fell ill with tuberculous meningitis. A lumbar puncture and microscopic examination revealed Koch's bacilli. The child died in 45 days and the girl who attended her succumbed three months after. The mother, who always was in close contact with these two children, continued to nurse them during her pregnancy. She gave birth to a very healthy boy whom she suckled herself in spite of the fact that she was suffering from a very severe cough, and against the urgent advice of her medical attendant to get a wet-nurse for the baby. The latter became ill in his fourth month of life with an influenzal attack which developed into broncho-pneumonia, death occurring 35 days after. Koch's bacilli had been found in the sputum. By this time the mother was suffering from greatly advanced pulmonary tuberculosis, and falling again pregnant gave birth to a healthy girl but died a few days afterwards. Thus, in the course of two years four persons succumbed in this unhappy family to tuberculosis transmitted from one member to the other.

Mortality Returns for April.

The number of deaths during the month of April amounted to 1907. Of this number, 147 died from tuberculosis, which seems to be an unusually large proportion. 96 cases succumbed to acute diseases of the respiratory organs, 32 to typhoid fever, nine to measles, eight to cerebro-spinal meningitis, and nine to small-pox. These figures, as well as the above statistics, are taken from *La Pédiatrie en Turquie.*

May 14th

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

A Memorial Research Fund to the Late Dr. Bull.

THE committee appointed to decide upon a fitting memorial to Dr. William T. Bull has reported in favour of the creation of a large fund ($500,000) for conducting original research under the direction of the College of Physicians and Surgeons, a department of Columbia University. It is not to be devoted to the erection of buildings and laboratories, but to the payment of adequate salaries. The committee states that the purpose of this memorial foundation is to unite to the great centres of practical surgery in New York a department where organised study of such work can be carried on from its various standpoints of pathology, bacteriology, physiology, and anatomy, and where facilities for necessary experimental work exist, and where the recording and publishing of results and findings may be effected. It is peculiarly fitting that the College of Physicians and Surgeons should be intrusted with this memorial, as Dr. Bull was its professor of surgery, and a great part of his most active years was devoted to its service. The College also furnishes the Department of Surgery with its affiliated departments, and in addition the laboratories of pure science of the University. In possessing access to these laboratories, presided over by men of recognised ability, with clinical facilities afforded by the hospitals, this foundation will have unsurpassed advantages for research work.

The Result of Trials of the Insane by Juries.

Dr. Robert W. Lamb, superintendent of the State Hospital for Insane at Matteawan, New York, has followed the history of 34 inmates of that institution who have been discharged as sound in mind by juries. 14 of this number returned eventually, either to prison or to the asylum; eight became troublesome to their families; three were unable to earn a livelihood; six disappeared; two committed suicide; and only a single one of the 34 was able to support himself partially after his discharge. Dr. Lamb states that in all cases referred to which have been submitted to juries for verdict the finding has been uniformly in favour of the insane person. He proposes as a remedy for this method of discharging insane criminals that the release shall require a certificate of two competent medical examiners and the approval of a judge of record. He very truly says it is a mistaken kindness to the individual, as well as a grave injustice to society, to turn adrift an irresponsible derelict, incapable of correct conduct.

Economy in Hospital Management by Cooperation.

The representatives of 45 hospitals in Greater New York held a conference recently to consider a plan of coöperation in the purchase of supplies. The proposed method of procedure was presented by a former purchasing agent of two of the largest railroads in the country. The plan consists of establishing a bureau with its officers which should be devoted to the purchase and distribution, on requisition, to the several hospitals of the usual supplies. It was shown that the method of wholesale purchase in the open market which such a central purchasing agency would adopt would diminish the cost to each hospital, compared with the present method, one-third to one-half. The maintenance of this agency was estimated to cost $24,000, and the saving annually to the hospitals would be $161,000. The plan was approved by the conference and the approval of the boards of management of the hospitals represented was strongly recommended.

The Increase of Psychopathic Hospitals.

One of the most striking evidences of progress in the scientific treatment of the insane in this country is the rapid increase of psychopathic hospitals. In these institutions those admitted are placed under the immediate observation and treatment of physicians skilled and experienced in nervous diseases, and as most of the patients are "suspects" rather than confirmed cases of insanity, large numbers recover without being certified as insane, as formerly, when thousands of "border-line" patients were rushed directly from their homes to the asylums. The reports of the psychopathic hospitals in this State, New York, show an astonishing number of discharged patients compared with the total received. The State of Illinois has established a psychopathic hospital in connexion with each asylum, on which large sums of money have been expended for construction and modern equipment. Other States are building or agitating the question of the necessity of such hospitals, and the future outlook indicates a great advance in the scientific treatment of the insane and the rescue of thousands from commitment to the old-time asylum.

May 10th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Hospitals and Snake-bite.

WHILE the recent Bombay Medical Congress was discussing remedies for snake-bite, the Madras Government was considering measures for bringing them within easier reach of the people, and a definite scheme with this object has just been approved. At first it was intended to prosecute the investigations of snake venoms and their antidotes at the Coonoor and Guindy Medical Institutes, but this proposal has been abandoned for lack of adequate equipment and staff. The second part of the scheme, however, will be carried out, and it provides that a stock of antivenene shall be kept in all hospitals in the Presidency and its availability advertised by every means possible, even down to the beating of tom-toms through the villages. The Madras proposals leave on one side, apparently, the Lauder Brunton treatment for snake-bite with lancet and permanganate of potash, but this treatment is so difficult of effective application in many cases that it can as yet hardly be recommended as trustworthy. The antivenene supplied will be the polyvalent variety recommended by Lamb and based on the theory that the six common terrestrial poisonous snakes of India can be roughly divided into two classes and the effects of all their bites efficaciously treated by the one antivenene. The great difficulty will be to get the people to take advantage of the facilities for treatment, which must, of course, be applied very quickly after the injury has been inflicted. The Madras Government is doing all that is possible to meet both these points, and the progress of its experiment will be watched with great interest in other parts of India, where, if the measure is successful, it might also be adopted.

The Calcutta Death-rate.

The total number of deaths registered in Calcutta during the week ending March 27th, 1909, was 1110, against 881 and 865 in the two preceding weeks, and higher than the corresponding week of last year by 232. There were 143 deaths from cholera, against 101 and 98 in the two preceding weeks; the number is higher than the average of the past quinquennium by 41. There were 61 deaths from plague, against 77 and 80 in the two preceding weeks. There were 446 deaths from small-pox during the week, against 305 in the previous week. There were 24 deaths from tetanus, against 19 in the previous week. The mortality from fevers and bowel complaints amounted to 162 and 24 respectively, against 76 and 45 in the preceding week. The general death-rate of the week was 68·0 per 1000 per annum, against 58·8, the mean of the last five years. The death-rate calculated on the estimated population was 58·4 per 1000.

Vaccination Fees.

Under the Bengal Vaccination Act natives who require the services of a public vaccinator (hospital assistant) at their houses have to pay 4 annas per head. Some of the middle-class Bengalis are now agitating to have this fee either abolished or reduced to a nominal fee of 1 anna, as they say that in large families vaccination involves an expenditure of more than some of them can bear. Many of the middle-class native women do not like to attend the local dispensary for vaccination, but prefer to be vaccinated in their own homes. The result of the present 4 anna fee, they state, is that they only get vaccinated once in their lives, revaccination being rare. This is a serious matter, as small-pox is practically endemic in parts of India, and revaccination every five years is desirable for those living in infected localities.

Plague in the Punjab.

Although plague is reported from a considerable number of districts in the Punjab, there is only one in which the mortality is really serious. This is the Ferozepur district, where between 400 and 500 deaths are occurring weekly, or more than one-fourth of the total in the province. Ludhiana, Lahore, and Montgomery districts and Patiala State each return about 100 deaths weekly. The mortality in the Punjab for the week ending March 20th was 1316, and since then there has been a slight rise, but the epidemic is happily much less severe than of late years. Its effect, therefore, upon the labour market should not be felt to any great extent, which is a fortunate circumstance, as a splendid harvest has to be reaped within the next few weeks.

Plague in Bombay.

The report of the Bombay health officer for the past quarter states that the mortality was lower by 1352 than in the corresponding quarter last year, and the difference in the figures between now and the mean of the corresponding quarters since plague began is very considerable. The report states that the destruction of rats, inoculation, and other preventive measures have been vigorously pressed. The large scale on which the rat campaign has been organised is shown by the fact that 100,000 rats were sent to Parel Laboratory for examination during the past quarter. Inoculation, however, does not become any more popular, and a smaller number of inoculations is reported than was performed in the corresponding quarter of last year. The report also shows that the port health officer and President of the Haj Committee have coöperated with the executive health officer in checking the spread of infection from small-pox brought by pilgrim ships from Jeddah.

Plague in the Central Provinces.

The Chief Commissioner of the Central Provinces in a recent communication to the Government of India drew special attention to those places in which plague persists, with the object of its extirpation and so preventing a spread from such places. The Inspector-General of Civil Hospitals is of opinion that unless endemic foci exist in Berar it must be held that the Central Provinces and Berar are annually infected from the Khandesh district of the Bombay Presidency, where the disease seems to linger practically throughout the year. Almost all the officers consulted agree in the opinion that plague is best held at a distance by (1) sanitary improvement; (2) systematic and continuous rat destruction; (3) prompt evacuation on the appearance of rat mortality; and (4) inoculation. The Inspector-General of Civil Hospitals holds the same opinion, and he recommends that measures (2) and (4) should be simultaneously practised. These measures are already put into practice and are receiving increasing attention, both by the Government and by local bodies. The special plague officer, Captain J. Morrison, though not able to fix precisely on any localities as foci, puts forward the unusual suggestion that in the towns of Akola and Khamgaon, the latter in the Buldana district of Berar, an examination of musk rats should be made during the period of abatement of human plague in order that the presence of plague infection among the rodents may be searched for and detected. This suggestion appears to contain a good practical means of arriving at some satisfactory data, for if it can be shown that during the period of abatement of human plague the rats caught in such places as are suspected of being distributing foci are suffering from plague or have on them plague-infected fleas, and at the same time rats caught in non-suspected places are free, the Chief Commissioner thinks that a great stride forward will have been taken, and the administration may probably be in a position to concentrate its plan of campaign upon these foci of infection. The Inspector-General of Civil Hospitals recommends that this investigation should be carried out at the following localities in Berar: Amraoti, Badnera, Akola, Akot, Khamgaon, and Shegaon. The Chief Commissioner will direct that officer to take measures accordingly during the next plague abatement period.

Plague Returns.

These returns for the week ending April 10th show 4419 deaths, against 4684 in the week preceding. Bombay Presidency reports 731, Bengal 288, the United Provinces 687, the Punjab 2044, Burma 82, and the Central Provinces 81. The Rajputana returns show 471 deaths, but these are for a fortnight.

The Pasteur Institute of Southern India.

This institute is making steady progress. The second annual report shows that 340 cases were treated in the year 1908–09, as against 180 in the 11 months preceding. In these 340 cases there were only two failures, though two cases which developed hydrophobia during treatment are not included in the statistics. Of the total number of patients 51 were Europeans, 39 were Eurasians, and 253 were Asiatics. The report states that the institute buildings are still unfinished and cannot yet be taken over by the committee. The year opened with a balance of about 3000 rupees and a large debt due to the Madras Government, but the Government wrote off their outstanding claims against the institute, and the year closed with a credit balance of Rs. 94.3. In addition to the ordinary expenditure of the institute a sum of about Rs. 14,000 is required for additions to the plant and extension of the quarters provided for indigent patients.

April 27th.

Medical News.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At a meeting of the Comitia of the Royal College of Physicians on April 29th and of the Council of the Royal College of Surgeons on May 13th Diplomas of L.R.C.P. and M.R.C.S. were respectively conferred upon the following candidates, who have passed the Final Examination in Medicine, Surgery, and Midwifery of the Examining Board in England and have complied with the by-laws:—

Adolphe Abrahams, [illegible] versity and St. Bartholomew's Ho[illegible] Leach Allott, Sheffield and Leeds [illegible] ed Ansari, B.A., M.B., Ch.B. Edin., [illegible] aring Cross Hospital; [illegible] ntab., Cambridge Uni[illegible] hn Lee Atkinson, Guy's [illegible] n Hospital; Bertram [illegible] tal; †Mark Bates, B.A. [illegible] rtholomew's Hospital; [illegible] mbay, Bombay Univer[illegible] mew's Hospital; Trevor [illegible] pital; William Francis Bowring, B.A. Cantab., [illegible] ospital; Eldred Curwen [illegible] omas [illegible] College, Cardiff, and St. Bartholomew's Hospital; Malcolm Donaldson, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Archibald Wallace Duncan, St. Mary's Hospital; George Hunter Dunn, M.A. Cantab., Cambridge University, King's College and St. Mary's Hospitals; Leslie Wilson Evans, Durham University and Guy's Hospital; Thomas Evans, Guy's Hospital; Philip Charles Field, University College, Bristol, and Guy's Hospital; Howell Woodwell Gabe, Middlesex Hospital; Edward Brown Garrard, Birmingham University; Paul Knighton Gilroy, B.A. Ca[illegible] St. George's Hospital; [illegible] n., Oxford University an[illegible] don Greaves, Queen's Univers[illegible] Harry Spencer Hall, B.A. Cantab., [illegible] David John Harries, [illegible] University College H[illegible] Zealand, New Zealand [illegible] Hudson, Manchester [illegible] Hughes, Guy's Hospita[illegible] Cambridge University [illegible] Patrick Hutchinson, [illegible] Michigan University [illegible] Percival Jones, Uni[illegible] College Hospital; [illegible] tholomew's Hospital; [illegible] Bombay University and St. Bartholomew's Hospital; Henry Goff Kilner, Middlesex Hospital; Septimus Joseph Lee, Middlesex Hospital; *Arthur Salusbury MacNalty, [illegible] University College Hospital; Reginald [illegible] B.A. Cantab., Cambridge University [illegible] Hospital; James Knowles Milligan, [illegible] Howard Edward Hall Mitchell, Guy's Hospital; Edwin Bertram Morley, University College and [illegible] L.D.S. Eng., University College, Bristol; Ralph Daniel O'Leary, M.B., Ch.B. Melb., Melbourne University and Middlesex Hospital; Douglas George Spring Rice Oxley, London Hospital; George Frank Page, St. Bartholomew's Hospital; Robin Pearse, St. Bartholomew's Hospital; Lionel Banks Perry, Cambridge University and St. Thomas's Hospital; Roger Aiken Rankine, Guy's Hospital; Alexander Armstrong Rees, M.B., Ch.B. Liverp., Liverpool University; Edward Douglas Whitehead Reid, B.A. Cantab., Cambridge University and St. Bartholomew's [illegible] Bombay University, King's College and University College Hospitals; Norman Guy Hawtrey Salmon, Charing Cross Hospital; August Carl Schulenburg, M.[illegible] versity and Guy's Hospital; C[illegible] Cambridge University and [illegible] Shenstone, B.A., L.M.[illegible] ia University; Samuel Shephe[illegible] Gordon Smith, St. Bartholomew[illegible] Smith, Manchester University [illegible] Ernest Richard Stone, B.A. Cantab., Cambridge University and Guy's Hospital; Thomas William Ramsden Strode, Charing Cross Hospital; William Francis Sutcliffe, St. Thomas's and Middlesex Hospitals; [illegible]; Henry Ashbou[illegible] ity and King's [illegible] b., Cambridge [illegible] nwright, Middle[illegible] College, Bristol, [illegible] d Ward, Westm[illegible] ng Cross Hospita[illegible] Thomas's Hospita[illegible] utta University and St. Bartholomew's Hospital; Robert Noel Woodsend, University College Hospital; and Thomas Strethill Wright, M.A. Oxon., Oxford University and St. Thomas's Hospital.

* M.R.C.S. granted on April 1st last.
† L.R.C.P. granted on May 13th last.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the First Professional Examination in Anatomy and Physiology for the Diploma of Fellow held on May 6th, 7th, 11th, 12th, 13th, and 14th, 113 candidates presented themselves, of whom 40 per cent. were approved and 60 per cent. were referred. The following are the names of the successful candidates:—

James Wilmot Adams, B.A. Cantab., L.R.C.P., M.R.C.S., Cambridge University and St. Bartholomew's Hospital; Andrew Blair Aitken, M.B., Ch.B. Glasgow, Glasgow University and London Hospital; Emmanuel Caeton Alles, L.M. & S. Ceylon, Ceylon Medical College and King's College; Frederick William Aris, M.D., C.M. Bishop's College, Montreal, L.R.C.P., M.R.C.S., Montreal and London Hospital; Henry Leo Barniville, B.A. Royal University of Ireland, Dublin University; Richard Henry Barter, Queen's College, Cork; Henry Cuthbert Bazett, B.A. Oxon., Oxford University and St. Thomas's Hospital; James Leatham Birley, B.A. Oxon., Oxford University and St. Thomas's Hospital; Walter Rowley Bristow, M.B., B.S. Lond., L.R.C.P., M.R.C.S., St. Thomas's Hospital; William Archibald Campbell, M.B., Ch.B. Glasg., L.R.C.P., M.R.C.S., Glasgow University and London Hospital; Anandrai Keshavlal Dalal, L.M. & S. Bombay, Bombay University and King's College; David Leighton Davies, M.D., M.S. Lond., L.R.C.P., M.R.C.S., Cardiff and University College Hospital; George Ernest Elkington, Birmingham University; John Henry Farbstein, M.B., B.S. Lond., L.R.C.P., M.R.C.S., University College; Thomas Gerald Fenton, L.R.C.P., M.R.C.S., St. Thomas's Hospital and King's College; George Ernest Oswald Fen[illegible] L.R.C.P., M.R.C.S., [illegible] versity and University [illegible] B.S. London, Sheffield [illegible] A., Royal University of [illegible] dining, Guy's Hospital; [illegible] Oxford University and [illegible] gh, L.R.C.P., M.R.C.S., [illegible] ott Henley, M.B., B.C. [illegible] n, M.B., [illegible]

Durham University; James Barlow Macalpine, L.R.C.P., M.R.C.S.,

Bartholomew's Hospital.

At an *ordinary meeting* of the Council of the College on May 13th Licences to practise Dental Surgery were conferred upon 30 gentlemen who have passed the necessary examinations and have complied with the by-laws, viz.:—

Herbert George Balls, Middlesex and National Dental Hospitals.

Stuart, Guy's
Royal Dental
University;
Royal Dental
versity; and
University,

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following candidates have passed the Primary Dental Examination:—

D. J. Doolin, A. R. Mallet, and R. K. Mulderry.

The following have passed the Final Examination and have been admitted Licentiates in Dental Surgery:—

R. S. H. Drabble, H. A. E. Noble, and L. F. Schlegel.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Alfred Neumann, Director of the Surgical Department of the Friedrichshain Hospital, has been granted the title of Professor.—*Bonn:* Dr. Reichenbach of Breslau has been appointed Extraordinary Professor of Hygiene, in succession to Dr. Kruse, who goes to Königsberg.—*Budapest:* Dr. Paul Kuzmik, *primarius* of the Surgical Department of St. John's Hospital, has been promoted to the chair of Surgical Operations.—*Clausenburg:* Dr. Josef Imre has been appointed to the chair of Ophthalmology.—*Giessen:* Dr. Johann Georg Mönckeberg, *privat-docent* of General Pathology and Pathological Anatomy, has been promoted to an Extraordinary Professorship.—*Halle:* Dr. Fritzel has been appointed to the charge of the Aural Polyclinic, in succession to Dr. Schwartze.—*Munich:* Dr. Robert Rössle has been appointed Prosector of the University Pathological Institute.—*Tubingen:* Dr. Bruno Fleischer, *privat-docent* of Ophthalmology, has been promoted to an Extraordinary Professorship.

SCHOOL CANTEENS.—The report of the canteen sub-committee of the Hastings education authority on the working of the Education (Provision of Meals) Act, 1906, has been issued. The committee has no reason to be dissatisfied with its work. From Nov. 2nd, 1908, to March 31st, 1909, no fewer than 60,706 meals were provided. The total cost of food was £367 4*s.* 1*d.*, and the cost per meal (food only) 1·45*d.* The meals provided were breakfasts, and it was found that the children so fed were far more eager for their studies than heretofore. Every assistance was given by numerous voluntary agencies, and care was taken to prevent

xation of parental duty and responsibility. As the

harge to the rates was the cost of the food only it

very well be said that the meals were a noticeable

to the rate.

's HOSPITAL MEDICAL SCHOOL (UNIVERSITY

NDON).—Mr. R. A. Chisholm has been appointed

Research Student for research in connexion with

ect of cancer.

HAM UNIVERSITY MEDICAL GRADUATES'

TION.— of this asso-

will tak The meeting

held at W., and the

dinner at the Café Royal, Regent-street, at 7.30.

THE May dinner of the Edinburgh University Club of London will take place at the Criterion Restaurant on Friday, May 28th, at 7.30 o'clock, Mr. S. H. Butcher, M.P., being in the chair. The Lord Advocate, Sir Henry Craik, M.P., and Mr. Barry Pain, are amongst the guests who have accepted invitations to be present.

WEST LONDON POST-GRADUATE COLLEGE.—The annual dinner of the Post-Graduate College and Past and Present West London Hospital will be held on Wednesday, June 16th, at the Trocadéro Restaurant, Piccadilly-circus, W., at 7 for 7.30 P.M. The chair will be taken by Dr. P. S. Abraham. The price of the dinner ticket is 7*s.* 6*d.* (exclusive of wine) and all past and present members of the hospital are invited to attend, and tickets may be obtained upon applying to the Dean of the College, Mr. L. A. Bidwell.

MIDWIVES ACT COMMITTEE.—The twelfth meeting of the Departmental Committee appointed by the Lord President of the Council to consider the working of the Midwives Act, 1902, was held at the Privy Council Office on May 12th, Mr. Almeric W. FitzRoy, the clerk of the Council, being in the chair. The following witnesses attended: Mr. Sydney Stephenson, F.R.C.S. Edin.; Dr. Sidney Barwise, county medical officer of health of Derbyshire, on behalf of the public health committee of the Derbyshire county council and on behalf of the Midland Medical Union; and Mr. Walter Schröder, deputy coroner, County of London Central District. The thirteenth meeting of the Committee was held at the Privy Council Office on May 19th. The following witnesses attended: Dr. A. Rivers-Willson, Mr. E. Parker Young, and Mr. J. Theodore Dodd.

THE FRENCH HOSPITAL: THE ANNUAL DINNER.—The annual dinner of the French Hospital was held at the Hotel Cecil on May 15th. His Excellency the French Ambassador presided, and was supported by the Spanish Ambassador and many other members of the "Corps Diplomatique." The Lord Mayor and Sheriffs were also present, and about 300 subscribers. Among the members of the staff of the hospital were Dr. George Ogilvie, Mr. Edmund Owen, Dr. L. Vintras, and Dr. H. Dardenne. In proposing the toast of the evening His Excellency announced that the very large sum of £4820 had been collected and this in spite of the present financial depression. He eulogised the untiring energy of the stewards, specially mentioning the large sums collected by Mr. A. Judah and Mr. E. Roehrich, both members of the committee. He also congratulated Mr. Pondepeyre, the secretary of the hospital, on his skilful management of the expenditure during the past year. In fact, the weekly expenditure on in-patients, apart from out-patients, was less than in any other hospital in London. The toast of the "Corps Médical" was responded to by Mr. Edmund Owen in felicitous terms, and to demonstate how well the patients were fed he invited any gentleman present to come to lunch at the hospital, provided they did not all select the same day. Dr. Ogilvie's name was not on the toast list, but on being asked by the French Ambassador to make a few remarks he said:—

> J'ai toujours suivi le principe du pauvre Coquelin, qui disait: "Je n'entreprends jamais un rôle avant de l'avoir étudié à fond." Ce soir je me trouve dans l'obligation de manquer à ce principe; car, un simple désir de son Excellence est un ordre pour moi, et bien que n'ayant pas étudié mon rôle, je vais tâcher de balbutier quelques paroles. Je me sens ce soir comme un métaphysicien écossais. Savez-vous, Messieurs, ce que c'est qu'un métaphysicien écossais? C'est un aveugle, cherchant à tâtons, dans une chambre obscure, un chat noir, qui ne s'y trouve pas. Mon crâne c'est la chambre obscure, et mes idées le chat noir. En effet, Messieurs, mes pensées s'en sont allées, comme à l'automne les feuilles jaunes tombent du chêne; elles s'en sont allées dans l'azur

léger, et comme un songe éphémère, elles n'ont laissé derrière elles—aucune trace. Me trouvant dans une telle condition, ce que j'ai de mieux à faire, c'est de m'asseoir, et de me taire. Avant cela cependant, permettez moi de vous donner mon opinion sur les devoirs d'un médecin. Son premier devoir c'est de prévenir le mal; s'il n'y réussit pas—de le guérir; et s'il n'y réussit pas non plus—de soulager la souffrance et de prolonger la vie. Je finirai, Messieurs, en répétant les mots, non d'un métaphysicien écossais, mais d'un grand mathématicien français—Descartes—"S'il est possible de perfectionner l'espèce humaine, c'est dans la médecine qu'il faut en chercher les moyens."

The proceedings then terminated.

Presentation to a Medical Man.—The officers and staff of the Devon County Asylum, Exminster, have presented Mr. Arthur Nathaniel Davis, L.R.C.P., L.R.C.S., L.M. Edin. (the medical superintendent), and Mrs. Davis with a solid silver centre piece and four vases, as a mark of respect and esteem on the occasion of the celebration of their silver wedding.

Donations and Bequests.—The Sheffield Town Trustees have made grants of £2000 to the Jessop Hospital for Women and £1000 to the Queen Victoria Nursing Association.—Under the will of the late Lieutenant-Colonel James Miller the Radcliffe Infirmary, Oxford, will receive £500.—By the will of the late Mr. Robert Low the Westminster Hospital and the Brompton Hospital for Consumption and Diseases of the Chest will receive £500 each, and St. Mary's Hospital, Paddington, and the West London Hospital, Hammersmith, £200 each.

Jubilee Nursing Congress.—A jubilee congress of district nursing was held in Liverpool on May 13th, the present year being selected on account of the late Mr. William Rathbone having inaugurated an organisation of trained district nurses in that city in 1859. The proceedings of the congress were conducted in three sections dealing respectively with: (1) the history of district nursing; (2) maternity work in connexion with district nursing; and (3) coöperation with boards of guardians, charity organisations, and public health departments. In the first section three of the 12 speakers were Miss Amy Hughes, the Countess of Aberdeen, and Mr. W. J. P. Giddings (editor of the official journal of the Royal British Nurses' Association in Australia). In the second section, which was presided over by Dr. Richard Caton of Liverpool, Dr. Helme read a paper and a number of ladies spoke. In the third section, at which Princess Louise and the Duke of Argyll were present, papers were read by Dr. Arthur Shadwell, Dr. E. W. Hope, and Mr. D. F. Pennant. There was a very large attendance, including delegates from British colonies, from the United States of America, and from many parts of continental Europe. In the evening there was a reception at the Art Gallery.

Death from Veronal Poisoning.—An inquest was held recently at Uxbridge on the body of a man who was alleged to have died from an overdose of veronal. It appears from the evidence at the inquest that the deceased had been in the habit of taking veronal tablets to induce sleep, and that subsequent to an attack of influenza he had suffered from severe pains in the head as well as from great depression, to combat which he took increased doses of the drug. One witness (a maidservant of the deceased) stated that her master told her that he had taken 124 grains of veronal. Dr. F. E. Walker, who attended the deceased, said that the man could not have taken more than 100 grains, as the box and bottle produced would not contain more than that quantity. When he was called to the deceased (some hours after he had taken the large dose) he found him comatose. He remained in that condition until he died two days later. Dr. Walker further said that he understood the deceased had been in the habit of taking four tablets a night, which was equivalent to 30 grains. He considered death to be due to the overdose of veronal. Further evidence was brought forward which showed that the large quantity of the drug had been taken accidentally, and a verdict of "Death by misadventure" was returned. We call attention to this case as of late there have been several instances of the causation of toxic symptoms by veronal. It seems probable that in the present instance the blame of the occurrence must rest with its victim in taking a lethal amount of the drug. But unpleasant effects have been observed from more reasonable doses, and it seems necessary to utter a warning that the administration of this as of all other hypnotics, should be closely watched. The public appear to be too fond of prescribing veronal for themselves.

A Cornish Centenarian.—Mr. James Carne, parish clerk of St. Columb Minor-with-Newquay, celebrated the 103rd anniversary of his birthday on May 3rd.

Deaths of Eminent Foreign Medical Men.—The deaths of the following eminent foreign medical men are announced:—Dr. G. L. Wynkoop, an eminent New York surgeon, from appendicitis.—Dr. Frank W. Draper, professor of forensic medicine in Harvard University.—Dr. Sockeel, formerly surgeon to the Douai Hospital.—Dr. Dujardin-Beaumetz, formerly inspector-general of the French Army Medical Service.—Dr. Albert Guttstadt of Berlin, Privy Medical Councillor and senior member of the Department of Medical Statistics. He enjoyed also the titular rank of professor. Most of his published works were of a statistical character, but he wrote festal essays for the Natural Science Congress of Berlin, 1890, and for the Chicago Exhibition in 1893 and "dictionaries" of Prussian and German hospitals. He founded, and assisted in founding, a number of societies of a medical and charitable nature, and was much interested in all sanitary and temperance movements.—Dr. Stecoulis, the medical adviser of the Dutch Legation and the Dutch delegate on the Board of the Sanitary Council at Constantinople, died last week. He was a well-known personality in the European circles of Pera and for a long time acted as President of the Imperial Society of Medicine.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The State Registration of Nurses.

Mr. Asquith's reception of the deputation on the State registration of nurses was courteous. In his reply he maintained a certain degree of reserve, and he committed himself to no course of action. He only promised careful and sympathetic consideration of the arguments put before him. What the deputation precisely asked was that the Government should give Parliamentary facilities to the Nurses' Registration Bill recently introduced into the House of Commons by Mr. Munro-Ferguson, but at present marked "dropped" in the official papers of the House. Sir Victor Horsley argued that the Bill had behind it a great volume of opinion in the medical profession. Mr. Asquith put several questions to him to elicit the strength of medical opinion on the subject, but although the cross examination was somewhat searching the Prime Minister afterwards characterised Sir Victor Horsley's speech as a very able one. Replying to the contention that the Bill was practically uncontroversial, Mr. Asquith enumerated a number of hospital authorities who were opposed to it, in addition to a section of medical men. What attitude the Government will take up towards legislation on the subject is obscure. Some time ago a suggestion was made that all three Bills relating to the registration of nurses should be read a second time, and referred *en bloc* to a select committee to examine and report upon. This course would not be incompatible with the reply of the Prime Minister. At the same time it must be evident to all observers of current Parliamentary affairs that the programme of the Government is so full this season that Mr. Asquith is little likely to give any facilities to Bills of private Members which do not command complete unanimity in all quarters of the House of Commons.

Medicines and the Spirit Duty.

Mr. Lloyd George has received representations on the increased duty on spirits from the Pharmaceutical Society of Great Britain. The increase of duty is reflected in the increased price of certain medicines.

Medical Men and the Petrol Duty.

It is not improbable that a deputation will be received by the Chancellor of the Exchequer with the object of discussing the peculiar case which medical men who use motor-cars have for an abatement of the petrol duty. The time of Mr. Lloyd George is well allocated up to the Whitsuntide holidays, and it is understood that he is not free to receive such a deputation until these are concluded.

The Royal Commission on Whisky.

The Royal Commission on Whisky and other Potable Spirits will probably present its report in a very few weeks. It has heard all the evidence which it is desired to take, and Lord James of Hereford, the chairman, has intimated that no time will be lost in formulating the report. As the Commissioners showed by their interim report in June of last year, they have reached definite conclusions on the applicability of the term "whisky" to various products of distillation. Their final report will show how they regard the limitations expressed by such terms as "Scotch whisky," "Irish whisky," "grain whisky," and "malt whisky." The Commissioners inquiry included other potable spirits besides whisky. They heard evidence on brandy, rum, geneva, and gin A portion of their report will therefore contain passages relating to these spirits.

Local Education Authorities (Medical Treatment) Bill.

This Bill, which proposes to enable local education authorities to recover the cost of the medical treatment of children provided under Section 13 of the Education (Provision of Meals) Act, 1907, has passed through one of the Standing Committees of the House of Commons.

HOUSE OF COMMONS.

WEDNESDAY, MAY 12TH.

Milk Legislation

Mr. **STANIER** asked the President of the Local Government Board when the Government would bring in its milk legislation —Mr. **BURNS** replied: I cannot fix a date at present, but I shall introduce the Bill as soon as I can.

Mr. **SNOWDEN**: May I ask whether the right honourable gentleman is [illegible] a great number [illegible] on the distinct [illegible]

THURSDAY, MAY 13TH

Mr. H. C Ross and the Egyptian Sanitary Service

Mr. **RAMSAY MACDONALD** asked the Under Secretary of State for Foreign Affairs whether Mr H. C Ross had to leave the Egyptian [illegible] that the Director-General was not prepared to promise him a permanent post in the inspectorate in Cairo

Seizure of Foreign Meat at Grimsby

Mr **STARKEY** asked the President of the Local Government Board [illegible] hether he [illegible] led I am [illegible] meat at [illegible]

STATE REGISTRATION OF NURSES.

A [illegible] Society for the State Registration of Trai[illegible] Prime Minister in his private room [illegible] May 13th The object of the [illegible] professions and of Members of [illegible] Lord Ampthill, Mr Munro [illegible], Sir William Macewen, Dr [illegible] P., Sir Luke White, M.P., Mr Ramsa[illegible] Mr. Smeaton, M P, Mr Field, [illegible] Hospital), Dr Bedford Fenwi[illegible] Prime Minister was accom[illegible] and several officials of Government Departments.

Lord **AMPTHILL** introduced the deputation and explained to the Prime Minister [illegible] had been in pr[illegible] siderable suppo[illegible] subject In 18[illegible] legislation for t[illegible] The principle h[illegible] means of discriminating between the value of the various kinds of certificates which were issued by the different hospitals and training schools. The public could discern no difference between the certificate [illegible] hospital [illegible] of affairs [illegible] those for [illegible] t on the same footing as members of other professions who stood in an [illegible] the medical and dental [illegible] To bring in a Bill?

Lord **AMPTHILL** No, sir, not to bring in a Bill but to give us facilities for one

Mr **ASQUITH** Is there any Bill now pending before either House?

Lord **AMPTHILL** There are three Bills at present There is Mr [illegible] ed as representing the British Medical Association The Association had on repeated occasions passed resolutions practically unanimously approving of the principle of the registration of nurses

Mr **ASQUITH** You do not say that there is anything like unanimity on the subject

Sir **VICTOR HORSLEY**: Very nearly.

Mr **ASQUITH** Do you say that?

Sir **VICTOR HORSLEY**. Certainly. At an annual representative meeting of the British Medical [illegible] which it was borne in mind [illegible] t elected delegates to a repre[illegible] was entitled to speak the voice of the profession Even if it were to be admitted that the British [illegible] dical [illegible] erly [illegible] ited Kingdom

Mr. **ASQUITH** Is that provided in the Bill?

Sir **VICTOR HORSLEY** Yes

[illegible] Bills, those for whom he spoke also felt that the nurses should have an [illegible] which passed through the House of Lords last year and was this session introduced into the House of Commons by Mr. Munro-Ferguson, its principles had been accepted by the Privy Council, the Local Government Board, the Admiralty, and the War Office. The second Bill had been good enough to flatter the first Bill by taking most of its clauses wholesale He thought the only material difference was that the second Bill (Mr Findlay's) wanted a larger [illegible] various quarters on [illegible] views and those of [illegible] Scotland relative t[illegible] with the aim of bo[illegible] secure State regist[illegible] United Kingdom. They desired to obtain for the nurses a recognised standard of teaching and examination for the three kingdoms and that all nurses placed on the British Nurses Register would have equal rights to practise as nurses in any part of Great Britain. The reason why so many nurses recorded their votes for separate registration for Scotland was due to the widespread misapprehension of the clauses of the British Bills. Most of the Scotch nurses had at that time not seen the British Nurses Bills, and the statements which were current concerning them were erroneous and misleading, such for instance that the Scotch nurses would require to go to London to be examined, thus causing them to incur a considerable expense. In neither of the British Bills before Parliament was there such a proposal. On the contrary, each of these Bills had clauses dealing with the [illegible] [illegible]nt centres throughout [illegible] [illegible]ciation had already had [illegible] [illegible]d under its control with [illegible] conjointly had held e[illegible] work in a thoroughly [illegible] explaining the character of the British Nurses' Registration Bills by means of distribution of copies of these Bills, and by letters to the local press had been a decided change in the attitude of the Scottish nurses towards the one portal system for the United Kingdom, so that many of those who previously signed in favour of the separate Scottish Registration Bill had now signed in favour of a single portal system. As an example he instanced one hospital in Glasgow having about 150 nurses on the staff, the majority of whom had previously si[illegible] for Scotland; 120 of these had now sign[illegible] [illegible]ystem for the United Kingdom. In ad[illegible] [illegible] matron, and the assistant matrons had [illegible] This was not an isolated instance. In [illegible] [illegible]d about 600 signatures of medical men and nurses in favour of a single portal system for the United Kingdom. A separate Scottish Bill would act as a barrier to the progress of the Scottish nurse. If the Scottish nurses were to have separate registration that would confine them to Scotland. If they desired to practise in England they would require to pass a second examination in order to be admitted to the British Register. A reciprocal clause of registration would not likely be passed as it would meet with strong opposition from the predominant partner who was not ben[illegible] and probably would be damaged thereby. [illegible] granted legally it would not do away with [illegible] [illegible]roused that the Scottish nurses did not pass the British standard of examination, and such statement would not facilitate the gaining of appointments for Scottish nurses south of the Tweed. It would be stupid for a Scottish nurse going with a patient from Scotland to England to become suddenly an unregistered nurse with no recognition as a trained nurse the moment she crossed the border. The Scottish nurses were quite prepared to welcome and to [illegible] [illegible]mination that might be instituted by th[illegible] [illegible] agency of the British Bills, and they c[illegible] and Irish sisters equal rights of exercising their profession in any part of the United Kingdom so that they might have the opportunity of gaining such positions as their merits might secure.

Miss STEWART explained some of the reasons why the present position of affairs was most detrimental to trained nurses. She argued that [illegible] of a council to enforce a professional [illegible] be conduciv[illegible] [illegible]ire for State [illegible] nursing profession in Ireland. She and her [illegible] sidered that it was essential that a central governing body should be empowered to [illegible] nursing education.

Mr. FIELD, [illegible] Minister that all parties in Ir[illegible] a[illegible] o[illegible] h[illegible] House of Commons would support legislation.

Mr. ASQUITH, in reply, said that he had been pleased to have had an opportunity of receiving so important and representative a deputation and of listening to the views expressed by members of it on a subject with which he had not first-hand familiarity. He understood that the object of the legislation which the deputation was promoting was to provide by means of a representative council the machinery for the examination of persons who were taking up the nursing profession, to set up a register upon which the names of only those persons who had satisfied the examination test should be inscribed, and to provide under penal sanctions that thereafter no one should claim or assume to practise as a registered nurse who had not satisfied that test and had not come on the register. That would not in the least prevent, as he understood the proposal, other persons who had not complied with this test from pursuing the profession of nursing. It would not be the necessary effect of this legislation, as he gathered from what Sir Victor Horsley had said in his very able speech, that the nurse recognised by the State was the only person fit to nurse. The unregistered person, the free-lance, if he might so describe her, would still be in a position to pursue her profession and carry on her calling.

Sir VICTOR HORSLEY: The public will take her at their own risk.

Mr. ASQUITH: As they do now. She would not be entitled to describe herself directly or indirectly as a registered nurse. All present were agreed as to the importance—the growing importance—and the dignity of this great profession of nursing, and as to the magnificent and indispensable services that it rendered to the medical profession and to the cause of humanity in this country. He was certain there was not a man or woman amongst them who did not wish to see it kept up to the highest possible standard of efficiency as regarded [illegible] would com[illegible] but of every [illegible] to deal with [illegible] was the best [illegible] [illegible]hat England, Scotland, and Ireland were [illegible] legislation on the lines which [illegible] laid down [illegible] he was bound to have regard to reports which came to him from other quarters. What did he find? He had got before him a list of representative persons whose opinion was entitled to considerable respect but who were opposed to this legislation. He was not going to read the names of individuals, but the list included the chairman o[illegible] vice-president of the Royal Free [illegible] Middlesex Hospital, the chairm[illegible] Hospital, the chairmen of St. Mary's Hospital, the Hospital for [illegible] College Hospital, the West-End Hospit[illegible] System, the Royal Victoria Hospital, [illegible] College Hospital, the treasurer of St. T[illegible] of St. George's Hospital, and a number of signatures from other hospitals.

Mr. FIELD: You have none from Ireland.

Mr. ASQUITH: But when I am told [illegible] in your favour, the enumeration of t[illegible] that is not quite the case. The right [illegible] said that he had also got before him [illegible] members of the medical profession i[illegible] most eminent members of the profession, in many departments, particularly in obstetrics and in many departments of surgery, and of something like 120 members of the profession of the highest distinction in the provinces who were opposed to legislation of the kind which the deputation was promoting. He had in addition before him the names of 49 matrons in London hospitals and 109 matrons in provincial hospitals who were also opposed to it. He could not, therefore, possibly regard this as a unanimous demand on the part of those persons interested in hospitals, surgery, or nursing. The deputation would therefore agree with him that the Government must look upon the matter as quite controversial. It was not possible to treat this as one of those subjects on which all persons were agreed and on which legislation went through by general consent. Under those circumstances he did not think the deputation could expect him to do more than to promise to give most careful and respectful consideration to the arguments which had been put before him. He had not heard the other side, but he admitted that these arguments *primâ facie*, at any rate, were very cogent arguments indeed. Having regard to the composition of the deputation and the authority which it possessed, he could assure the members of it that their arguments would be most carefully and sympathetically considered by his colleagues and himself. But for the time being, in view of the facts which he had stated, the Government could not regard this as other than a question which required very detailed examination in view of all the interests concerned.

The deputation then withdrew.

MONDAY, MAY 17TH.

The Sanitary Services in India.

Sir WILLIAM BULL asked the Under Secretary of State for India whether the scheme proposed by the Government of India in its letter to the Bombay Government of Dec. 4th, 1907, on the subject of the improvement of the sanitary services in India and of the development of the existing establishments, was completed; and whether any, and if so what, special provisions were made therein to give effect to the view set forth in that letter that a sanitary service offered a suitable and congenial career for [illegible] and that by fully utilising that source [illegible] [illegible]id the expense of materially cr[illegible].—Mr. HOBHOUSE (on behalf of [illegible] [illegible]as not yet been completed. The [illegible] [illegible]rtance to the inclusion in any su[illegible] [illegible] and to which the honourable Member refers.

Medical Examiners in the University of Madras.

Mr. KETTLE asked the Under Secretary of State for India whether he could state the number of examiners for the medical degrees of the University of Madras; how many of them were Indians; and what was the remuneration received by each.—Mr. HOBHOUSE furnished the following written reply: The examiners are appointed by the University authorities and the Secretary of State has no official information as to their number [illegible] received by them: but it appears from the Cal[illegible] at in that year there were [illegible] was an Indian.

The Indian Medical Service.

Mr. KETTLE asked the Under Secretary of State for India whether the higher grades of the medical service of the Native States of India were generally filled by Indians to the satisfaction of the Government and the public; whether less than 10 per cent. of such positions in British-India were held by Indians; and whether he was aware that the exclusion of native [illegible] posts was regarded in India as part of [illegible] Government.—Mr. HOBHOUSE forwarded the following written answer: The Secretary of State has no detailed information on the first point, but he has no reason to doubt that the answer is in the affirmative. As regards the proportion of Indians in the Indian Medical Service, the honourable Member is no doubt aware that that service is recruited by competitive examination and is freely open to natives of India. It is further the policy of the Government to encourage the growth of an independent medical profession in India, and to throw open to the profession in general some of the appointments now held by members of the Indian Medical Service. The Secretary of State proposes shortly to present to Parliament papers on this subject.

Civilian Medical Practitioners and Military Medical Duties.

Earl PERCY asked the Secretary of State for War whether a number of civilian medical practitioners were employed for military medical duties at salaries of £150 a year or more; and whether the services of military medical officers on the retired list were available for the performance of these duties.—Mr. [illegible] furnished the following reply: One civilian medical practitio[illegible] [illegible]d salary of £150 a year. Others are employed a[illegible] with remuneration at capitation rates and the total fees in some instances and at some periods amount to £150 a year or more. In cases where a saving would be effected and retired officers can be found who are willing to undertake the work, appointments are offered to these officers at a fixed salary under Article 449 of the Royal Warrant for Pay, &c. About 70 retired officers are so employed.

TUESDAY, MAY 18TH.

[illegible] Officer of Health.

[illegible] or House Surgeon [illegible] former £100 per [illegible] rd, residence, and washing.

ASHTON-UNDER-LYNE, DISTRICT INFIRMARY AND CHILDREN'S HOSPITAL.—Assistant House Surgeon. Salary £90 per annum, with board, &c.

[illegible] House Surgeon. Salary [illegible]

[illegible] lent Assistant [illegible] edical Officer. [illegible] board, wash- [illegible]

CAPE COLONY, FRERE HOSPITAL, East London.—Resident Medical Officer. Salary £300 per annum.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's Inn-road, W.C.—Assistant Surgeon. [illegible] Salary £150 [illegible] ching.

[illegible] ary £100 per annum, with apartments, board, &c.

DUDLEY, GU[illegible] y £60 per annum.

DUMFRIES, [illegible] Research Fellow at [illegible] quarters, attendance, and laundry.

DURHAM COUNTY COUNCIL.—Three School Medical Inspectors (two females and one male). Salary in each case £300 per annum.

EAST AFRICA PROTECTORATE.—Two Medical Officers. Salary £400 per annum, with quarters.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—Pathologist and Registrar. Salary £100 per annum.

EXETER, ROYAL DEVON AND EXETER HOSPITAL.—Assistant House Surgeon, unmarried. Salary £60 per annum, with board, lodging, and washing.

GLASGOW, VICTORIA INFIRMARY.—Visiting Physician.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—House Surgeon. Salary £100 per annum, with board, residence, and laundry.

IPSWICH, EAST SUFFOLK HOSPITAL.—Senior House Surgeon. Salary £80 per annum.

KING EDWARD VII. SANATORIUM, Midhurst, Sussex.—Senior Assistant Medical Officer. Salary £150 per annum, with board, lodging, and attendance.

KING'S LYNN, WEST NORFOLK AND LYNN HOSPITAL.—House Surgeon. Salary £100 per annum, with board, residence, and washing.

LIVERPOOL, CITY OF, EDUCATION COMMITTEE.—School Medical Officer. Salary £250 per annum.

LONDON SCHOOL OF MEDICINE FOR WOMEN, 8, Hunter-street, Brunswick-square, W.C.—Demonstrator in Anatomy and Curator of the School Museum (females).

MEDICAL MISSION HOSPITAL, Balaam-street, Plaistow, E.—Assistant Doctor (female) for six months. Board, residence, and laundry provided.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead.—Junior Resident Medical Officer. Salary £50 per annum, with board and residence.

NOTTINGHAM GENERAL HOSPITAL.—Locum Tenens for three and a half months. Salary £45, with board, lodging, and washing.

OLDHAM INFIRMARY.—Senior House Surgeon. Salary £100 per annum, with residence, board, and washing.

PADDINGTON INFIRMARY AND WORKHOUSE.—Medical Officer for six months. Salary at rate of £100 per annum, with board, lodging, and washing.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N.—Honorary Anæsthetist.

REDHILL, EARLSWOOD ASYLUM.—Junior Assistant Medical Officer, unmarried. Salary £130 per annum, with board, lodging, washing, &c.

ROCHESTER, ST. BARTHOLOMEW'S HOSPITAL.—House Physician. Salary £110 per annum, with board and residence.

ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, Plaistow, E.—Honorary Anæsthetist.

SAMARITAN FREE HOSPITAL FOR WOMEN, Marylebone-road, N.W.—Anæsthetist. Salary £15 per annum.

SHEFFIELD, EAST END BRANCH OF THE CHILDREN'S HOSPITAL.—House Surgeon. Salary £70 per annum, with board, lodging, and washing.

SHEFFIELD EDUCATION COMMITTEE.—Assistant Medical Officer for Elementary Schools. Salary £250 per annum.

SHEFFIELD ROYAL HOSPITAL.—Honorary Assistant Surgeon.

SHEFFIELD UNION HOSPITAL, Firvale.—Resident Assistant Medical Officer, unmarried. Salary £100 per annum, with apartments, rations, &c.

SOUTHAMPTON, COUNTY BOROUGH OF.—Assistant Medical Officer of Health. Salary £250 per annum.

SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—House Physician. Salary £100 per annum, with rooms, board, and washing.

SUFFOLK DISTRICT ASYLUM, Melton.—Second Assistant Medical Officer, unmarried. Salary £160 per annum, with board, apartments, attendance, and laundry.

SUNDERLAND INFIRMARY.—House Surgeon. Salary £80 per annum, with board, residence, and washing.

TEIGNMOUTH HOSPITAL, S. Devon.—House Surgeon. Salary £70 per annum, with board, lodging, and washing.

THROAT HOSPITAL, Golden-square, W.—Resident House Surgeon. Salary £75 per annum, with board, residence, and laundry.

WALSALL AND DISTRICT HOSPITAL.—House Surgeon, also Junior House Surgeon. Salary of former £100 and of latter £80 per annum, with board, residence, &c.

WEST BROMWICH DISTRICT HOSPITAL.—Resident Assistant House Surgeon, unmarried. Salary £75 per annum, with board, residence, and washing.

WEST LONDON HOSPITAL, Hammersmith-road, W.—House Physician for six months. Board, lodging, and laundry provided.

WESTERN AUSTRALIA, STATE OF, MEDICAL AND HEALTH DEPARTMENT.—Medical Officer to the Central Board of Health. Salary £400 per annum.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Resident Medical Officer. Salary £100 per annum, with board, lodging, and laundry. Also Two House Surgeons. Salaries £80 per annum, with board, lodging, and laundry.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Farsley, in the county of York; and at Leith, in the county of Edinburgh.

Births, Marriages, and Deaths.

BIRTHS.

CUNNING.—On May 18th, at 3, Upper Wimpole-street, the wife of Joseph Cunning, of a son

MARETT.—On May 13th, at Avranche, St. Lawrence, Jersey, the wife of E. P. Marett, L.R C.P. Edin., of a son.

PHILLIPS.—On Sunday, May 16th, at 12, Iverna-gardens, Kensington, the wife of Llewellyn Phillips, M.D. Cantab., F.R.C.S., F.R.C.P. (of Cairo, Egypt), of a daughter.

DEATHS.

ELLABY.—On May 13th, at Harley-street, Charlotte Louisa Ellaby, M.D., aged 55 years.

WILSON.—On May 15th, at Dean's-grove, Guildford, James Wilson, late Lieutenant-Colonel R.A.M.C., in his 74th year.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE PRACTICE OF DENTISTRY IN THE PAST.

IN the current number of the *Proceedings of the Royal Society of Medicine*, which we reviewed in our last issue, Mr. Ashley Densham, the learned librarian of the Odontological Section, contributes an interesting historical review of the progress of dental science and literature, which he concludes by quoting a list of fees from the book of Paul Jullion, surgeon-dentist, 1781. The list forms so complete and surprising a conspectus of the field of dental surgery in the days of John Hunter that we reproduce it in full.

	£	s.	d.
Scaling the Teeth...	0	10	6
Bleeding and scarifying the gums...	0	5	0
Filling or stopping up the cavity of a decayed tooth with lead	0	5	0
Ditto with gold	0	7	6
Filing and polishing a tooth	0	2	6
Extracting a tooth or stump	0	2	6
Transplanting a living tooth	5	5	0
Ditto a dead tooth...	2	2	0
Engrafting the crown or body of a sound human *tooth on the root of a decayed one*	2	2	0
Constructing and fitting an artificial tooth with silken ligature	0	10	6
Ditto with gold wire fastenings	0	15	6
Ditto with gold spring	1	5	6

Fitting and fixing a human tooth on the same construction as an artificial one with silken ligatures.	2	2	0
Ditto with gold wire fastenings	2	7	0
Ditto with gold springs	3	3	0
Fitting an upper or an under row of human teeth on the same principle without fastenings	31	10	0
A complete set of human teeth with gold springs ...	73	10	0
Constructing and fitting an artificial palate	21	0	0
For the care and treatment required for preserving the health and vigour of the teeth, gums, and contiguous parts of a person's mouth at per year.	4	4	0

This comprehensive tariff gives rise, in our mind, to several reflections. Was it meant for the instruction of the public or was it intended only as a helpful guide to inexperienced practitioners diffident as to the value of their services? If the former, who would not have preferred to part with a quarterly guinea to obtain the prophylactic benefits of the last item on the table rather than risk a bill for £73 as a sequel to the unthinkable *nastiness* of wearing another person's discarded teeth? Then again, where did the "living teeth" for transplanting come from? Did any unscrupulous practitioner, when clearing a mouth in preparation for an artificial denture, ever venture to abstract a healthy tooth or so in addition to the carious offenders and fit his booty "still living" into an edentulous cavity in his next patient's jaw? Or were persons to be obtained willing to part with their healthy teeth to make good another's loss for a consideration easily paid out of the extra 3 guineas accruing to the dentist as the intermediary in the transaction? It is only fair on the period under review to add that the best professional opinion of the day was opposed to this process of grafting teeth, for, according to Mr. Densham, Thomas Berdmore, Dentist-in-Ordinary to King George III., who wrote the first English scientific treatise on dentistry, condemned the practice, argued that "if the replantation of teeth is so rarely successful, how much less can be the implantation of a tooth that can only roughly fit the socket and must ...... inevitably cause pain and inflammation." But however the "living" teeth came into the dentist's hands it is easy enough to imagine the source of the "dead" teeth in a century notorious for its judicial executions. Doubtless, too, the battlefields of Europe paid full toll to the traffic in human teeth, though Mr. Densham is inclined to believe that the "resurrection men" were the chief agents in their collection. It is hardly surprising to read later in his paper that "in 1774 a chemist named Duchâteau, living near Paris, found the colour and odour of his ivory denture so unpleasant that he conceived the idea of having it modelled in porcelain," which gave rise to experiments in which he was associated with Dubois de Chémant, a Parisian dentist who subsequently took all the profit from them in London where he made and sold a "mineral paste" which was the forerunner of the materials used in the manufacture of the perfect artificial teeth of the present day.

In the tariff which we have quoted it is noteworthy that no mention is made of amalgam fillings, which were a contribution of the nineteenth century to dentistry; Mr. Densham, however, attributes the first use of gold leaf for filling dental cavities to Giovanni d'Arcoli, professor at Bologna and Padua, who flourished in the fifteenth century. If we are to accept Mr. H. E. P. Platt's interpretation of a passage from Cicero's second book, "De legibus,' the use of gold in prosthetic dentistry dates back as far as the XII tables of the Roman law which were drawn up by the decimvirs in 450 B C Mr Platt says in his fascinating little book "A Last Ramble in the Classics "The Twelve Tables contained provisions against extravagance at funerals and among them a direction that gold should not be thrown on the funeral pile But an exception was expressely made of gold stopping in a tooth This might lawfully be buried or burned with the corpse 'In lege cum esset 'neve aurum addito' quam humane excipit altera lex "cui auro dentes vincti escunt, ast im cum illo sepeliet uretve, se fraude esto' We should hesitate to differ from Mr Platt on a question of pure scholarship but on historical grounds we are not convinced that "vincti can be rendered legitimately as "stopped ' We have heard the suggestion that the word referred to the ornamental binding of the teeth with gold foil It would surely be as correct to consider it a reference to gold "bar and bridge work as to the process of filling carious cavities with gold But however this may be, Mr Densham has shown in his studious paper that many dental processes have a longer pedigree than some of their modern practitioners would be inclined to put to their credit

THE SANITARY SANCTION FOR CIRCUMCISION

To the Editor of THE LANCET

SIR,—In your issue for May 8th the writer of an article on "Circumcision maintains that this measure was adopted by the ancients rather for sanitary than for religious reasons In this connexion the following quotation may be of interest It is from Philo Judaeus the famous Alexandrian contemporary of Christ: Περι Περιτομῆς (De Circumcisione) [Editio Mangeyana II, 211]: There are for circumcision four chief reasons the first being freedom from a grievous disease and from suffering hardly to becured, which they call carbuncle [*sic*] (obtaining the appellation as I think from its burning on in a smouldering fashion) and which is more prone to happen to those who have prepuces * * * I am Sir, yours faithfully,

The London Hospital, E, May 12th 1909 W H PALMER

A HEARTLESS EXPERIMENT!

THE following spirited protest may interest those of our readers who were present at the recent conversazione of the Royal Society of which we gave an account in our last number Others may have seen a report of the experiment to which our anonymous correspondent refers in some of the daily newspapers, one of which at least published an illustration of the animal in question undergoing its ordeal by electricity To those who are not aware of the recent dedication to science of the bulldog "Jim by his distinguished master, we suggest that some light might be thrown on the matter by a study of Dr Augustus Waller's paper on Einthoven's studies made with his string electrometer which will be found on another page We would also commend the letter that follows as an elegant model to the antivivisection propagandists throughout the country —

To the Editor of THE LANCET

SIR —I think it only right to bring before your notice an experiment of a vivisectional nature although it did not involve actual cutting which was performed at the Royal Society *soirée* last night by a well known physiologist before an audience which included, shame be it said, at least two bishops The subject was a bulldog A strong leather strap plentifully provided with sharp nails was secured around his neck and one fore and one hind foot were immersed in vessels containing water charged with that intensely corrosive metal sodium and that very poisonous gas chlorine An electric current caused by the anxious throbbings of its heart passed through the whole body of the animal and out through the vessels and by some devilish device these throbbings were exposed to view upon an illuminated screen No anæsthetic of any kind was employed and this went on for hours

I am Sir yours faithfully,

INDIGNANT

CUT THROAT IN RELATION TO SPEECH: A MEDICO LEGAL POINT

To the Editor of THE LANCET

SIR —I shall be glad if you would kindly publish the following in your columns as I am desirous of ascertaining what would be the general opinion on the point The subject is of great importance from the medico-legal point of view and I can find no recorded opinion directly bearing on it

In July last a boy was injured in a village in this district shortly before daybreak His throat was cut across and the larynx divided just *above* the vocal cords The wound severed the facial and lingual arteries and also divided the anterior wall of the oesophagus He lingered till sunset. Shortly after the infliction of the injury he is alleged to have spoken and made a statement involving certain persons The nearest medical officer sent for (a medical subordinate serving under me) did not arrive till after the boy was dead He saw the injuries and held the post mortem examination He gave out as his opinion that the gaping wound of the throat rendered speech impossible from the moment of its infliction Before the case went into court he sought my advice and I fully concurred in his opinion Medical opinion to the contrary was, however obtained from outside the district by the defence It was stated by this authority that the wound 'being situated *above* the vocal cords, it would not have prevented the boy from speaking fairly loudly and [illegible] ally grow fainter as the [illegible] ound can be produced when the cut is *above* the vocal cords, but can it be held that *speech* would also be possible under the circumstances? Sound must surely be modulated in the mouth for the purposes of speech Will your readers kindly tell me if they are of opinion that any sound produced in a case like this will reach the mouth and be converted into speech in the presence of a large gaping wound, the presence of blood, possible falling in of the soft parts above shock of the injury, depressed mental state of the injured, and other attendant circumstances?

I am Sir, yours faithfully,

R K MITTER M B, Major I M S,
District Medical and Sanitary Officer

Salem India, April 27th 1909

*** Our correspondent is correct in thinking that in such a case as he describes the voice of the victim would be much impaired but we cannot agree with him that it would be impossible for a bystander to understand anything the patient said Even though the injury to the larynx were very complete and the wound gaped greatly, yet it is almost certain that a portion of the expired air would pass into the mouth and would give rise to sufficient voice to be heard and understood Such an extensive cut-throat wound is unusual as a homicidal injury in this country at least it is nearly always suicidal, and all who have had experience of such cases will agree that nearly always, even where the injury has been very extensive, it is quite possible to understand what the patient is saying —ED L

A MEDAL FOR HEROIC CONDUCT

A CORRESPONDENT has forwarded to us for inspection a silver medal awarded last year to Mr J H Robinson for courageous conduct by the Hamburgischer Verein ' Seefahrt, together with the covering letter received by Mr Robinson from Herr Ballin, the well known director of the North German Lloyd Line We print an illustration

of the striking design on the obverse of the medal The reverse [illegible] letter —

[TRANSLATION]

Hamburg, September, 1903

Dr John Hargreaves Robinson, Southport

The [illegible] of your [illegible] *Nord Se* [illegible] established as a reward for exceptional performances at sea We herewith bring this decision to your knowledge and at the same time beg to inclose to you the medal. BALLIN Director

MEDICAL MEN AND THE CLERGY IN RELATION TO "CHRISTIAN SCIENCE"

AT the Bath and Wells Diocesan Conference on May 14th Mr Stephen [illegible] said that it was a false philo [illegible] of healing The clergy were [illegible] fantastical jargon Medical men could not [illegible] "Christian Science should be fought in the open [illegible] medical practice In practice it all depended on what the two men were in daily life If the clergyman and the doctor were good friends understanding each other honouring each other, not meddling not libelling not gossiping but backing each other up there would be no want of coöperation at the bedside. But if the two men did not like each other, never lent a book to each other, had to be far apart at the feast, and never met for a pipe and a talk, then, of course, the unhappy, innocent patient had to suffer from the stiffness of etiquette manifesting itself over his prostrate form. It all began when the man was quite well, and it was then that events happened which settled whether the clergyman and the doctor would, or would not, coöperate over his sick bed. As to the clergyman, not being sent for until the last, that was a matter for the family, not for the doctor. The doctor and the clergyman must coöperate against "Christian Science," not when people were ill, but when they were well. Take a village where the Lady Bountiful was a "Christian Scientist," the two men must coöperate to make her faith and works a positive burden to her. They must laugh her pretentions to scorn, and explain to people that she was dangerous and show where she had gone wrong. The worst of quarrels was better than letting "Christian Science" spread through a village. "Christian Science" had nothing to do with being ill. It got at people when they were well; it loved prominence, razzle-dazzle, and advertisement. After severely criticising the claims of certain faith-healers, and stating that doctors could not coöperate with such people, Mr. Paget asked what the clergy were going to do when a doctor was hostile or indifferent and left a case. If the patient died the clergyman would be landed with all the difficulties of the Peculiar People. How long would the clergyman continue the treatment? To what cases would he apply it? A mother might bring a child with a cleft palate or a hare lip, what would the clergyman say? There were, Mr. Paget argued, a whole range of diseases in which it would be as futile to expect good results from "Christian Science" as in those of physical malformation he had referred to. He did not deny that faith, hope, and love might somehow help a man to hang on in a case of typhoid fever or diphtheria until he had brewed in his own system sufficient antitoxin, or had had it injected into him, but he did not believe that faith, hope, and love made any difference to the germ of which the disease was the work, or to the brewing of the toxins or antitoxins once the germs got in. It was a chemical process and could be reproduced in a rabbit or a test-tube.

YELLOW FEVER IN BRITISH HONDURAS IN 1905.

To the Editor of THE LANCET.

SIR,—With reference to your note on p. 1433 in THE LANCET of May 15th we have to say that we published Sir Rubert Boyce's report in 1906. It was circulated in this country and copies were sent to the press. The copy we sent you was reviewed in your journal dated May 12th, 1906. The report is published at 3*s.* 6*d.* net, and copies can be obtained through a bookseller or direct from us.

We are, Sir, yours faithfully,
J. AND A. CHURCHILL.

Great Marlborough-street, London, W., May 14th, 1909.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

MONDAY.

ODONTOLOGICAL SECTION (Hon. Secretaries—H. W. Trewby, D. P. Gabell, J. Howard Mummery): at 8 P.M.

Paper:

Mr. Warwick James: A Preliminary Note on the Eruption of the Teeth.

TUESDAY.

MEDICAL SECTION (Hon. Secretaries—Herbert P. Hawkins, A. M. Gossage): at 5.30 P.M.

Papers:

Professor R. T. Hewlett: The Treatment of Typhoid Fever with an Anti-endotoxic Serum.

Dr. E. W. Goodall and Dr. Bruce: The Results of Treatment of Cases of Typhoid Fever with the same Anti-endotoxic Serum.

FRIDAY.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—Hugh Lett, E. I. Spriggs, Harold J. Stiles): at 4.30 P.M.

Papers:

Dr. Parkes Weber: Congenital Obliteration of the Bile-ducts with Cirrhosis.

Mr. A. R. Thompson: Congenital Dislocation of Hip.

Cases:

Dr. Eric Pritchard: (1) Unilateral Hypertrophy of the Hand; (2) Symmetrical Helical Fistulæ with Branchial Fistula in an Infant.

Mr. Sydney Stephenson: A Case of Oxycephaly.

Dr. George Carpenter: (1) Case of Congenital Morbus Cordis; (2) Specimen of Congenital Hypertrophic Stenosis of Pylorus.

And other Cases.

N.B.—Fellows of the Society are entitled to attend and to speak at all Meetings.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. H. G. Adamson: Clinique (Skin). 5.15 P.M., Lecture:—Dr. F. J. Smith: The Treatment of Typhoid Fever.

TUESDAY.—4 P.M., Dr. C. T. Williams: Clinique (Medical). 5.15 P.M., Lecture:—Dr. T. N. Kelynack: Open-air Schools for Tuberculous Children (with lantern slides).

WEDNESDAY.—4 P.M., Mr. R. Johnson: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. R. W. Allen: The Pathology and Treatment of a Common Cold.

THURSDAY.—4 P.M., Sir Jonathan Hutchinson: Clinique (Surgical). 5.15 P.M., Lecture:—Sir John Broadbent, Bart.: Relation of Arterio-Sclerosis to Aneurysm and Renal Disease.

FRIDAY.—4 P.M., Mr. E. Clarke: Clinique (Eye).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Lecture:—Surgical Registrar: Demonstration of Cases in Wards. 12 noon, Pathological Demonstration:—Dr. Bernstein. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eyes. 2.30 P.M., Operations. 5 P.M., Lecture:—Mr. Lloyd: Anæsthetics.

TUESDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 12.15 P.M., Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Saunders: Clinical (with cases).

WEDNESDAY.—10 A.M., Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Saunders: Diseases of Children. 12.15 P.M., Lecture:—Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Harman: Diseases of the Eyes. 2.30 P.M., Operations. Dr. Robinson: Diseases of Women. 5 P.M., Lecture:—Dr. Beddard: Medicine.

THURSDAY.—10 A.M., Lecture:—Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eyes. 2.30 P.M., Operations. 5 P.M., Lecture:—Mr. Dunn: Cases of Eye Diseases.

FRIDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. Lecture:—Medical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. Abraham: Cases of Skin Diseases.

SATURDAY.—10 A.M., Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Saunders: Diseases of Children. Mr. Harman: Diseases of the Eyes. 12.15 P.M., Lecture:—Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. 2.30 P.M., Operations. Dr. Robinson: Diseases of Women.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, *Prince of Wales's General Hospital, Tottenham, N.*

MONDAY.—Clinics:—10 A.M., Surgical Out-patient (Mr. H. Evans). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Nose, Throat, and Ear (Mr. H. W. Carson); X Rays. 4.30 P.M., Medical In-patient (Dr. A. J. Whiting).

TUESDAY.—Clinic: 10 A.M., Medical Out-patient (Dr. A. G. Auld). 2.30 P.M., Operations (Mr. Carson). Clinics:—Surgical Out-patient (Mr. W. Edmunds); Gynæcological (Dr. A. E. Giles): 4.30 P.M., Lecture:—Dr. B. Price: The Various Forms of Congenital Heart Disease and their Diagnosis.

WEDNESDAY.—Clinics:—2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. H. W. Carson); X Rays. 3 P.M., Medical In-patient (Dr. G. P. Chappel). 4.30 P.M., Lecture:—Mr. H. W. Carson: Catarrhal Deafness.

FRIDAY.—10 A.M., Clinic:—Surgical Out-patient (Mr. H. Evans). 2.30 P.M., Operations (Mr. W. Edmunds). Clinics:—Medical Out-patient (Dr. A G. Auld); Eye (Mr. R. P. Brooks). 3 P.M., Medical In-patient (Dr. R. M. Leslie).

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Sir Dyce Duckworth: Medicine. 3.15 P.M., Mr. Turner: Surgery. 4 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. Carless: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye. 3.30 P.M., Special Lecture:—Mr. Cargill: Glaucoma, its Symptoms, Physical Signs, and Pathology.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. Sale-Barker: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 2.15 P.M., Special Lecture:—Dr. R. Bradford: Hemiplegia. 3.15 P.M., Special Lecture:—Mr. McGavin: Psoas Abscess, its Origin [illegible] Treatment.

SATURDAY.—[illegible] Out-patient Demonstrations:—10 A.M., [illegible] 11 A.M., Eye.

WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM, 73, Welbeck-street, W.

MONDAY.—3 P.M., Clinical Demonstration: Dr. H. Campbell.

TUESDAY.—5 P.M., Clinical Demonstration: Dr. J. Mackenzie.

WEDNESDAY.—3 P.M., Clinical Demonstration: Dr. F. Palmer.

THURSDAY.—3 P.M., Clinical Demonstration: Dr. T. D. Savill.

FRIDAY.—2 P.M., Clinical Demonstration: Dr. P. Stewart. 5.30 P.M., Clinical Demonstration: Dr. E. Macnamara.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY.—3.45 P.M., Lecture:—Dr. Kingsford: Anæsthetics.
FRIDAY.—3.45 P.M., Lecture:—Mr. W. Wallis: Mouth and Teeth.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Clinical Lecture.—Dr. F. E. Batten: Cerebellar Disease.
FRIDAY.—3.30 P.M., Clinical Lecture:—Dr. W. A. Turner: Epilepsy.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET, at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

An original and novel feature of "The Lancet General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready *means of finding any notice* but is in itself an *additional* advertisement.

Advertisements (to insure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in The Lancet.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, *Mr. Charles Good, The Lancet Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions* should be addressed.

The Lancet can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. *Advertisements* are also received by them and all other Advertising Agents.

A Clinical Lecture

ON

HYPERNEPHROMA.

Delivered at University College Hospital on Feb. 10th, 1909,

By WILFRED TROTTER, M.S. Lond.,
F.R.C.S. Eng.,
SURGEON TO THE EAST LONDON HOSPITAL FOR CHILDREN; ASSISTANT SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

Gentlemen,—The increased attention which is now being directed, on account of the revival of the controversy as to their origin, to the class of renal tumours known as hypernephromata has led me to take a case of such a tumour of the kidney recently under my care as a text for this afternoon's lecture. I shall divide what I have to say into two chief parts. In the first I shall give a very brief summary of the case I have just mentioned, then deal shortly with the naked-eye anatomy of these tumours as exemplified characteristically in the specimen from this case, and finally with the clinical features of the disease, which are for the most part obvious corollaries of the morbid anatomy. In the second part I shall describe the chief microscopic characters of these tumours, showing you on the screen the structure of the specimen in this case and then shortly discuss the hypotheses of the pathogenesis of hypernephromata.

Part I.

Clinical history of case.—The patient, a man, aged 54 years, was admitted under the care of Dr. F. J. Poynton, who kindly transferred the case to me. There was a history of pain in the left side of the abdomen coming on especially after heavy meals and lasting for about one and a half hours. The patient had been subject to this pain for about five months. For about a month longer he had noticed occasional attacks of stabbing pain over the region of the heart. The attacks lasted for from five to ten minutes. There had [illegible] occasional passage [illegible] was thin and unhealthy [illegible]ation showed no striking change the appearance of the skin and mucous membranes suggested a pronounced anæmia. A tumour was present in the left loin. It was of about the size of a cocoanut, roughly globular in shape, fairly uniform in outline, and elastic in consistence. It filled the loin from behind and was resonant in front. The tumour was distinctly tender. The temperature rose every evening to about 100° F. The urine was normal. The case was regarded as one of pyonephrosis or tumour. On Dec. 28th I explored the swelling through a lumbar incision, found it to be a tumour, and removed it with the kidney from which it grew. The patient recovered rapidly, the large wound healed by first intention, and at the time of discharge, three weeks later, the general health was much improved and there was no pain or other evidence of disease. The tumour, which was of about the size of a cocoanut, proved to be a hypernephroma. The specimen shows the characteristic naked-eye features of these growths.

We may now enter upon some general account of the hypernephromata. The classification of the tumours of the kidney has always been one of the most difficult and thankless tasks of the morbid histologist. The possible varieties of structure have seemed almost too many even to be enumerated and too varied to be generalised. For a long time the histology of these tumours consisted of a number of [illegible]

step in advance was made in the classical work of Grawitz, who showed that a large number of the most widely different histological pictures were different aspects of one and the same tumour. He showed that it is a characteristic of this tumour to display in different parts structures of the most different kinds, but that through all its varieties a thread of similarity runs which renders the recognition of it at all times easy and certain. He went further, however, and produced a considerable amount of evidence to show that these tumours might be correlated with the well-known existence in the kidney of small islets of tissue identical in structure with the suprarenal body, and sought in fact to demonstrate that the tumour originated in these ectopic masses of suprarenal tissue. His contention was generally accepted and has remained until quite recently uncontested, so that the tumour to-day goes by the name of Grawitz's tumour or, more widely, hypernephroma. We shall mention later some of the chief arguments used by Grawitz to support the hypothesis of the suprarenal origin of these tumours.

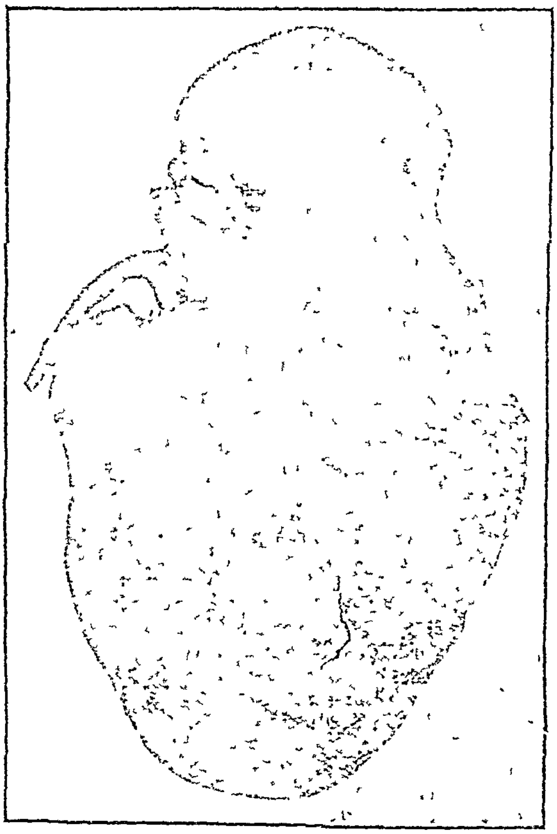
For a considerable time it was supposed that the hypernephroma was a comparatively rare tumour. The increase of experience which has come with the rapid diminution in the mortality of nephrectomy has, however, shown that this opinion was not justified. The various series of cases of malignant disease of the kidney which are published from time to time have shown an increasing proportion of hypernephromata to the whole; this may be ascribed to increasing familiarity with the microscopical and macroscopical characters of the tumour, and the recognition of the fact that there are no tumours which vary in structure so much from part to part as do kidney tumours, and that therefore no kidney tumour can be regarded as adequately investigated until sections from many different parts of it have been examined. The increase in the cases classified as hypernephromata has occurred for the most part at the expense of those formerly described as carcinoma. Anyone at all familiar with the histology of the tumour can well understand how many hypernephromata may have been mistaken for carcinomata, for an isolated section may show a striking resemblance to a typical alveolar carcinoma. That this mistake has probably been common is well shown in an example quoted by Albrecht. In one of the cases published in Lotheisen's series the kidney was removed and the growth described as an adeno-carcinoma. Ten years later the patient died in von Eiselsberg's clinic in Vienna of a late recurrence in the bronchial glands which showed the characters of a typical hypernephroma. As to the increase in the num[illegible] that Perthes, w[illegible] the papers of C[illegible]erature, whereas now, after another 12 years, several hundred could probably be collected quite easily.

Putting together a few of the more recent series of cases of kidney tumour we find that out of 196, 146 were hypernephromata—that is, almost exactly 75 per cent. The remaining 25 per cent. are made up mostly of sarcomata, to a much less extent of squamous epitheliomata of the pelvis, while a true carcinoma of the kidney apart from hypernephroma is a very great rarity or possibly does not exist. The kidney tumours of children are practically all sarcomata; there is but one case on record of a true hypernephroma in an infant, and, as was long ago pointed out by Kuster, malignant disease of the kidney is a disease of earliest childhood and middle age, affecting but little young adults and the aged. Hence, we may lay it down definitely [illegible] common kidney tumour of adults [illegible] kidney tumour in an adult is [illegible] of this type than anything else. This is the only etiological fact bearing on the disease which we can regard as absolutely definite. There is, of course, the ubiquitous history of injury, but the conditions here make it even more than usually liable to suspicion. We know that the tumour may be present for a very long time before it is discovered, so that injury may come to have its apparent importance merely by calling attention to the part; moreover, it is very probable that it may induce a hæmorrhage from a kidney the seat of a tumour when it would not do so from a sound one.

Macroscopic anatomy.—The most striking characteristic of the naked-eye anatomy of these tumours is their tendency to show a more or less definite encapsulation. Pathologically, of course, there is n[illegible] tumour, except in ve[illegible] separable from the [illegible] substance even, the [illegible] partial separation may sometimes be effected. I have seen a case, for example, in which the dissection of the tumour out of the kidney seemed for a time during the operation to be feasible—though, of course, such an attempt had ultimately to be given up when the true nature of the disease became apparent. A second characteristic is that the tumours tend *to grow out of* the kidney, leaving very often a large part of the latter to all appearances normal. Ultimately the tumour breaks through its false capsule and extends diffusely in the surrounding tissues. In this specimen the encapsulation is for the most part quite well marked, but you will see that in one place the growth has come through and is involving the perinephral fat.

The growth then commonly appears as a smooth nodular or bossy mass projecting from the surface of the kidney which has become, as it were, an appendage of the tumour. (Fig. 1.) The latter, examined externally, is of a yellowish-white colour. Its substance varies from a considerable firmness, in which, however, there is always a certain element of elasticity on account of the presence of the capsule, to a definite fluctuation. Large cystic areas are not uncommon.

FIG. 1.



Anterior aspect of specimen. At the hilum the renal vein distended by growth can be seen. In front of the lower pole of the tumour is the part where the capsule had been broken through and the surrounding fat was being involved.

Mr. J. H. Kirk, Florence; Messrs. R. A. Knight and Co., Lond.; Messrs. J[illegible] and | Lond.; Mrs. A. M. Smith, H[illegible] St. Barth[illegible]

A section shows a very characteristic picture. The tumour displays a striking lack of homogeneity. It is irregularly cut up into lobules by slightly marked fibrous bands. The substance is mostly yellowish-white in colour, opaque, and of structureless appearance. Parts are more translucent and greyish-white, others softened and caseating. The most characteristic thing, however, is the presence of irregular patches and sometimes considerable areas of a bright yellow colour. These are not unlike the slough in a deep seated gumma, but are of irregular outline, of a brighter yellow, and not so tough. The picture is further diversified by the presence of areas of red or brown colour and granular or fleshy aspect; these are usually few.

The process of caseation may go on to the formation of considerable cysts. In the walls of such cysts calcification may sometimes be present—an evidence of the length of time these tumours may exist. The pelvis of the kidney is usually pressed on, and displaced, by the tumour. It is frequently stretched but not often dilated, while ulceration of the tumour into it is a rare and late manifestation. One more feature often present may be mentioned, and that is the early invasion of the renal vein by the growth; it is by no means unusual for the vein at the hilum of the kidney to be obviously distended by tumour substance growing within it. (See Fig. 1.) The nak[illegible] nephroma, then, are fairly [illegible] is usually recognisable at once with a considerable amount of certainty.

To resume, the most important characters are the encapsulation, the absence of diffuse infiltration of the kidney so that some part of the latter recognisably projects from the mass, the multiformity of the section, the presence of caseation and sometimes cysts, the bright yellow areas, and finally, in some cases, the invasion of the renal vein.

CLINICAL MANIFESTATIONS.

From the anatomical characters described above much of the clinical behaviour of these tumours may be inferred, while such features as are not directly to be correlated in this way are expressions of the rate of growth.

Duration and rate of growth.—All degrees of malignancy and all rates of growth are found. The tumour may reach a great size and produce widespread metastasis within a few months; on the other hand, it may develop extremely slowly, years may elapse between the appearance of the initial symptom and the recognition of the renal tumour clinically, again, many more years may pass and then a solitary metastasis appear. Distant recurrences—six, eight, or even ten years after the removal of the primary tumour—are not very uncommon, and similar intervals may elapse between the first hæmaturia and the recognition of the enlargement of the kidney by palpation.

Striking differences may occur between the rate of growth of the primary tumour and that of the metastasis. Albrecht, for example, records a case in which several years elapsed after the removal of a metastasis before the kidney became palpable—and this in spite of the fact that after the recognition of the nature of the metastasis repeated and most careful examinations had been made. The resemblance between the behaviour of these tumours and that of malignant disease of the thyroid is very striking, and has been frequently commented on. The extremely long periods that in some cases have elapsed between the occurrence of the first symptom and the recognition of the kidney tumour or the appear[illegible] metastasis has suggested that, like carcinoma [illegible] pernephromata may exist for many years as an apparently benign growth.

Symptoms.—It may be said in general that some symptoms are almost always present, that they are very rarely characteristic and often not even suggestive of the disease, and that they are much more usually misleading than helpful.

General.—The general health of the patient is not usually in any way affected until long after the existence of the tumour has become readily recognisable. Perhaps the commonest general sym[illegible]ptom, and the one most likely to mislead, is fever. A continued elevation of temperature to about 100° F. is not at all uncommon and may lead to a diagnosis of pyonephrosis, as I have known to happen several times.

Urinary symptoms.—In many cases these are entirely absent. Hæmaturia and lumbar pain are the commonest. The hæmaturia, when it occurs, is often profuse, tends sometimes to be associated with strain or local injury, and may spontaneously disappear for long periods. According to some authors, a minute trace of blood in the urine is very common. The pain is usually dull, aching, and continuous and not much influenced by rest or exercise. Renal colic may follow hæmorrhage or involvement of the renal pelvis by the growth leading to sudden obstruction.

Symptoms suggesting disease of neighbouring organs.—Intestinal and gastric symptoms are the commonest of these. Epigastric pain associated with digestion, nausea, vomiting, and loss of appetite may be present, and so definite as to give rise to some difficulty if there is no palpable tumour or its renal origin is not clear. In one of Albrecht's cases there were marked chemical alterations in the gastric contents and a formal diagnosis of carcinoma of the stomach was made. In the case reported here there was pain which seemed undoubtedly to be of gastric origin.

Evidences of involvement of veins.—Two such may be p[illegible] œdema of the legs and varicocele. The first is rare; I have known it once to be the first symptom which attracted attention. It is due to involvement of the vena cava.

nevertheless, may be of unequal distribution on the two sides. It might be expected to be commoner with right-sided tumours than with left, but I know of no statistical evidence of this.

Varicocele.—Since this sign was first pointed out by Guyon it has attracted much attention, and monographs have been written upon it, notably by Hochenegg. It is not a sign which I have seen to be of any special value. To be suggestive it should come on suddenly in a middle-aged man, and it should not vary in size with the position of the patient. Finally it is more frequent on the left side, more significant on the right.

THE TUMOUR.

This may be dealt with under three heads—the characters of the tumour as renal, the characters of the tumour as hypernephroma, and aberrant types.

As *renal* the tumour is in the loin, which it fills from behind, or can be displaced into the loin; is in contact with the posterior abdominal wall from the first and with the anterior wall only late, so that a hand laid on the loin meets with resistance at once, while one laid on the anterior abdominal wall must be depressed more or less before resistance is felt. In front is the colon which may, if the tumour is large, be felt, or otherwise be recognisable by percussion after distension per rectum with air; the colon lies over the lower inner angle of the mass. The tumour moves in respiration; its margins are rounded and its surfaces curved so that it cannot lie flat against the abdominal wall unless very large.

As *hypernephroma* the tumour is never very large, except in the latest stages when diagnosis is no longer difficult; typically it is rounded and but faintly bossy, well-defined, moveable with the diaphragm, by manipulation and with changes in posture; it is firm, tense, and elastic, and sometimes obviously cystic; it frequently has somewhere in its outline one large distinct boss—the kidney; at times there is marked tenderness. It resembles a hydronephrosis in distinctness of outline, mobility, elasticity, and possibly long duration, but it does not usually give the impression of a single uniform cyst, while even the cystic forms have harder parts in them. It resembles a pyonephrosis in being associated with fever and in the elasticity and tenderness, but it is more distinct and more bossy in outline, much more moveable, usually of longer duration, and is but rarely accompanied by the presence of pus in the urine. Occasionally the simulation of the clinical picture of pyonephrosis is almost irresistibly exact.

Aberrant clinical types: latency of the primary tumour.—The primary tumour may be absolutely symptomless, so that there may have been nothing to attract the patient's attention to it, and he presents himself to the surgeon for a secondary growth in some distant part of the body. Such a secondary growth is almost always in a bone and is quite usually single. The kidney shares with the prostate, the thyroid, and the breast the character of being an organ in which growths originate which tend in an especial degree to produce metastasis in bones, and with the thyroid the character of frequently producing a metastasis which remains solitary for a long period. Hence it is a valuable clinical maxim that a malignant growth of a bone in an adult should never be operated on without the condition of these two organs having been carefully considered. A further difficulty, however, may be met with. Not only may the primary growth be symptomless, but it may grow so slowly as to be quite inaccessible to palpation at a time when obvious metastasis has occurred.

Simulation of other tumours.—On the left side the growth has been mistaken for gastric, splenic, and colic tumours, in each case the mistake being facilitated by the presence of symptoms suggesting disease of the suspected organ. In one case known to me the tumour forming a very large projection from the convex border of the kidney had rotated into a vertical position so that the lower pole of the kidney projected forward and the recess between it and the tumour simulated very closely the notch in the anterior margin of the spleen. It is not necessary here to repeat the various diagnostic features of these different tumours; it is enough to [illegible] of a growth [illegible] l, deep, and [illegible] superficial and has a sharp edge.

So marked is the tendency to the production of single secondary growths that these cases, with perhaps some similar thyroid cases, are amongst the very few instances in surgery where a primary growth and a systemic metastasis may be operated on with a rational hope of obtaining a cure. The clinical characters, then, of this disease are such as to make failures in diagnosis extremely likely to occur, while these failures are exceptionally serious as they may lead the surgeon to overlook in its early stages a form of malignant disease which offers a reasonable hope of curability, or to embark upon dangerous and hopeless operations.

TREATMENT.

The indications for treatment when once the diagnosis is established are usually quite clear. A kidney containing a hypernephroma must be removed. However tempting it may appear to do a local resection of the kidney when the tumour is small, experience teaches that nothing less than a total nephrectomy is justifiable. In the absence of secondary growths mere size of the tumour should not be regarded as a contra-indication unless there is obvious involvement of other abdominal organs. In this connexion it is interesting to notice that although tumours of the colon suitably placed frequently involve the kidney, tumours of the kidney rarely involve the colon. Again, as already said, the presence of a *solitary* metastasis in an accessible position should not contra-indicate operation on that, and of course on the kidney.

The technical details of the operation must be designed so as to provide for four essential requirements. These are: preliminary exploration of the extent and connexions of the tumour and of the condition of the opposite kidney; free access to the tumour and especially to the pedicle; early division of the pedicle; and removal of the fatty capsule of the kidney with the tumour.

Preliminary exploration can only be carried out satisfactorily through a peritoneal incision, and is essential to [illegible] upon a dangerous and [illegible] pletion of it impossible. [illegible] early division of it are important for two reasons: first, the prevention of shock, which is very great if on account of an inadequate incision much pulling on the parietal peritoneum and pedicle is necessary; secondly, the prevention of the detachment of emboli of the growth during the manipulation—the actual occupation of the renal vein by growth being very common. Removal of the fatty capsule is an important precaution against recurrence, but it is unfortunately difficult to carry out, and one is tempted not to do it by the ease with which the tumour shells out.

The incision which best allows these various requirements to be carried out is, in my opinion, undoubtedly the transverse. If there is doubt as to the nature of the case the incision may be begun in the usual oblique direction in the loin. As soon as it is clear that a tumour of any size has to be dealt with the incision is carried transversely forwards, if necessary as far as the edge of the rectus. With the patient on the side and a large sandbag under the opposite loin, the wound gapes widely and affords admirable access to the tumour without any of the violent pulling and tearing which are so disastrous in these operations. Across the wound, somewhere about the plane of the anterior superior spine, if the tumour is of moderate size, the reflection of the peritoneum runs vertically. The peritoneum should now be incised in front of the reflection and the relations of the tumour explored intraperitoneally. If nephrectomy is decided upon, the posterior parietal peritoneum with the colon is pushed off the front of the tumour, the pedicle defined, tied in the usual three parts, and divided, care being taken to remove as much of the renal vein as is possible. Now the tumour with the surrounding fat can be removed without the usual dangers of shock or embolism. The peritoneal incision is closed, the fleshy muscles should be stitched in one layer, the external oblique in another, and a small drain brought out in the posterior angle of the wound.

The operation I have described was done in the case which has been my text to-day. The patient, although by no means in a very satisfactory general condition, had no shock whatever, the operation throughout was extremely easy, and the wound healed by first intention.

A word may be added upon prognosis. The mortality of nephrectomy for tumour is said to be about 25 per cent. In alveoli are fairly small and their contents solid and tightly packed. When the alveoli are larger and the packing is less tight, the cells stick to the vessels but disappear in large part from the rest of the spaces, so that the perivascular cylindrical structure already described is produced, and the cells no doubt being freer to grow are apt to produce the monstrous club-like forms. Degeneration of the cells of the tumour readily occurs, and it does not need the examination of many sections to show that degenerative changes have a special tendency to appear in the centre of the alveoli. Such a degenerating alveolus will be of large size, will show a peripheral zone of healthy cells several layers thick and a central mass of protoplasmic and nuclear débris. The picture then comes closely to resemble some of the tubular carcinomata of the breast in a striking way. Some of the alveoli showing this degenerative change are elongated and then give the picture of a tube lined by an irregular layer of cells and containing a central column of débris—the resemblance then to a swollen tubule of the kidney is remarkably close. The general arrangement is nevertheless obviously alveolar.

Tubular type.—In these parts of the tumour the structure is that of a columnar cancer; elongated ramifying spaces are present, lined for the most part by a single layer of well-formed cells of an irregularly cubical or columnar form. Papillary processes projecting into spaces may be very typically developed but do not as a rule show any great complexity of ramification. (Fig. 3.) The stroma here also for the most part consists of thin-walled vessels which run between the tubules. In general in this tumour the tubular parts show smaller and more regular cells than do the alveolar, so that the suspicion seems justified that the former is the essential type of the tumour and that the latter is derived from it secondarily.

The hypotheses of Grawitz and Stoerk.—The principal arguments of Grawitz in favour of the supposed origin of these tumours in suprarenal rests are summarised by Stoerk as follows. 1. The correspondence between the subcapsular situation of the tumour and that of the islets of suprarenal tissue which are found in the kidney. 2. The striking differences of the characters of the tumour cells from those of the renal epithelium. 3. The presence of fat in the tumour cells and in the cortical cells of the suprarenal and its absence from the kidney epithelium. At the outset of his criticism Stoerk [illegible] the [illegible] weighty questions, Why do hypernephro[illegible] in the kidney and never in the [illegible] secondly, Why are suprarenal tumours both be[illegible] always so different in structure from [illegible] He points out that islets of suprarenal tissue are found in the liver, but that hypernephroma never occurs there. He shows also that while the suprarenal islets are commonest in the upper pole of the kidney, hypernephromata affect chiefly the central part.

With regard to the subcapsular situation, he remarks that while suprarenal islets may occur actually within the substance of the fibrous capsule of the kidney, this is never the case even with the smallest hypernephromata. The supposed resemblance between the cells of the hypernephroma and those of the suprarenal Stoerk denies with the greatest emphasis. The "swollen cell" especially, which is the most characteristic feature of hypernephroma sections, is totally unlike anything found in the suprarenal body. It is true the hypernephroma cells show the presence of a doubly refracting substance, as [illegible] cells, but Stoerk adds that many other [illegible] show the same phenomenon. With these and other arguments Stoerk makes a very formidable attack upon the hypothesis of Grawitz, and he follows this up by showing that the hypernephroma is essentially a tumour of tubular structure tending t[illegible] of spaces and intracystic formations, [illegible] kind occurs in the suprarenal. Finally, he produces evidence to show that in the sma[illegible] masses found in kidneys undergoing [illegible] structures are to be found resembling [illegible] of the most characteristic parts of a hypernephroma, and he gives some very striking illustrations. He concludes, therefore, that the tumour must be classified as an adenoma, cystoma papillare, or carcinoma—*according to the form in which it occurs.*

It has not been possible in any way to do justice to Stoerk's paper, and I am fully aware that I have given but the roughest summary. Still, it will be obvious that the wor[illegible] for a very serious reconsideration of [illegible] tumours. Personally I hasten to [illegible] h up to the time of reading Stoerk's paper fully acquiescing in the accepted views, I have been a good deal impressed by his arguments, and I think they may be added to. There seems to be very little doubt that these tumours are essentially tubulo-cystic in structure; the specimen in the case reported here confirms this very strikingly, and shows, I think, clearly that the perivascular arrangement which seems at first sight the primary structure of the tumour is a secondary development.

What would appear to be a significant argument seems to me to follow from the very great relative frequency with which these tumours are now known to occur. When Grawitz first enumerated his views in 1883, the tumour was thought to be rare, but in 1905 we already find Albrecht saying that hypernephromata undoubtedly form the great bulk of kidney tumours and that, apart from epithelioma of the pelvis, carcinoma is of the greatest rarity. To-day it would probably almost be justifiable to say that all primary epithelial tumours of the kidney substance are of this nature This would leave us in the remarkable position of having to believe, if we maintain Grawitz's hypothesis, that in a glandular organ so subject to malignant disease as is the kidney, a true carcinoma of the gland substance does not occur. Moreover, many facts of the growth of these tumours are quite as consistent with the views of Stoerk as with those of Grawitz. For example, if the tumour originates in the convoluted tubules it must always be primarily in the cortex; again, the essential circulatory condition of its origin will be a slow venous blood current, the convoluted tubules receiving their blood-supply entirely through veins from the glomeruli, and its growth will begin in the most intimate relation to the purely venous networ[illegible] tubules. It is perhaps possible that h[illegible] int of the reason why the tumour shows [illegible] rare among the epithelial growths—to penetrate and spread within the veins, and an inclination to develop metastatically in bones so marked that it is nearly true to say that if there is a single secondary growth it will be in a bone

One of the most valuable lines of thought which are constantly being suggested by Stoerk's paper is the question as to what influence we may expect the original structure of an organ to exercise upon the structure of a carcinoma developing in it. It would seem probable *a priori* that the more elaborate the normal arrangement of the epithelium of a glandular organ is, the more complicated may we expect to be the picture which a carcinoma growing in it may present It is in this connexion perhaps suggestive that the only organ in the body approaching the kidney in the complexity of its tubular structure, and, like the kidney, maintaining its function until late in life, is the testicle. The complexity and multiformity of the tumours of the testis need no emphasising. A careful comparison of the structure of the tumours of the two organs from this point of view would probably yield much of interest, and at any rate perhaps justify the indulgence in speculation which suggests it

THE RESULTS OF A YEAR'S USE OF VACCINES IN GENERAL MEDICINE.[1]

BY W. HALE WHITE, M.D.,
SENIOR PHYSICIAN TO GUY'S HOSPITAL;
AND
J. W. EYRE, M.D.,
BACTERIOLOGIST TO GUY'S HOSPITAL.

WHEN your secretaries kindly asked us to bring before the society some subject of therapeutic interest it struck us that it might lead to a useful exchange of opinion if we laid before you every case which during the past year we have conjointly treated with vaccines, excluding those treated with tuberculin Our only reason for excluding these is that tuberculosis is usually such a slow disease that it is impossible to draw conclusions as to treatment until many months have elapsed. The following cases have all occurred since Jan. 1st, 1908. Those at present still under treatment are not included, but with that exception we give every case which we have jointly treated with vaccines, so that we may as far as possible arrive at a correct view of its value. We have grouped the cases under the following heads: A. Genito-urinary System; B. Alimentary System; C. Empyemata and Subdiaphragmatic Abscesses; and D. Miscellaneous.

---

[1] A paper read before the Therapeutical and Pharmacological Section of the Royal Society of Medicine on May 4th, 1909.

A. *Genito-urinary System.*

CASE 1.—The patient, a female, aged 49 years, married, had suffered from multiple arthritis for nine months. It had been regarded as osteo-arthritis. No benefit had followed any of many lines of treatment. The gonococcus was not isolated from the vaginal discharge, but the index to it was 4·0; therefore she was treated with a stock trivalent gonococcal vaccine in doses of from 5,000,000 to 10,000,000 at intervals of seven days. Three doses were given. The arthritis entirely subsided and she was discharged cured at the end of a month.

CASE 2.—The patient, a female, aged 30 years, married, had suffered from multiple arthritis for three weeks. The gonococcus was isolated from the urethra. The patient was treated with trivalent stock vaccine. She received three doses of 5,000,000, 5,000,000, and 7,500,000 respectively at intervals of six days. She was discharged cured, and when seen three weeks later was quite well.

CASE 3.—The patient was a male, aged 36 years. First attack of gonorrhœa. Two months later arthritis followed, and when the patient was seen it had existed two months. Many joints in the body were affected. The gonococcus was isolated from the urethra and the patient was vaccinated with a vaccine prepared from his own gonococcus. Four doses varying from 5,000,000 to 25,000,000 were given at *intervals of six days. He was discharged cured, and when* seen three weeks later was quite well.

CASE 4.—A male, aged 26 years. First attack of gonor- [illegible] the urethra and a vaccine was prepared. Owing to the number of generations that elapsed before the gonococcus was isolated in a state of purity larger doses than usual were employed. The patient received three doses of 100,000,000, 100,000,000, and 200,000,000 respectively at intervals of 12 days. The opsonic index varied during this period from 0·7 to 3·6. The arthritis entirely disappeared in five [illegible]

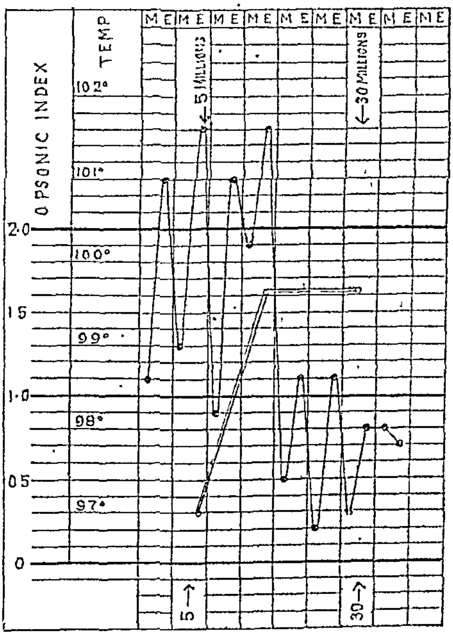
CASE [illegible] ears, seen with I[illegible], had five weeks before we first saw her begun to suffer from pains and swelling in many joints. Remedies for gout were tried but did not relieve. The ears and the bridge of the nose became swollen and double conjunctivitis supervened, followed at the end of four weeks by severe cystitis, with blood and pus in the urine, and high temperature and pain over the bladder and both kidneys. When first seen by us she was very ill with cystitis and double pyelitis, vomiting, rapid pulse, and high temperature. She was so ill that it was thought likely that she would die. *Bacillus coli communis* was isolated from the urine and a vaccine was prepared, the index to the organism being 0·35. A 5,000,000 dose of the vaccine from her own *Bacillus coli communis* was followed by a rise of the index to 1·6. Four days later a dose of 30,000,000 was injected, followed after ten days by a dose of 250,000,000. Improvement began directly after the first injection. The patient made an uninterrupted recovery, and when we saw her a year later there had been no return of the trouble. The range of temperature is well shown on the accompanying chart. (Chart 1)

CASE 6.—The patient, aged 26 years, seen on March 18th, 1909, with Inspector-General J. J. Dennis, R.N., had had enteric fever from Christmas, 1908, to the middle of February, 1909. From Feb. 15th to 25th the temperature had been normal; then high evening and low morning temperatures suggestive of pus prevailed, and had continued ever since. On March 15th pus appeared in the urine and the right kidney became tender. *Bacillus coli communis* and *Staphylococcus albus* were found in the urine, and vaccines of each were prepared. The index was 1·45 to *Bacillus coli communis* and 0·44 to the *Staphylococcus albus*. A dose of 5,000,000 of the patient's own *Bacillus coli communis* vaccine was injected on March 20th. By March 23rd the temperature had become normal, and another dose of 5,000,000 was given, and a dose of *Staphylococcus albus* vaccine of 100,000,000. On March 29th there was still some pus in the urine and a dose of 100,000,000 *Staphylococcus albus* vaccine was given, and on March 31st a dose of 10,000,000 *Bacillus coli communis* vaccine was given. No further treatment was necessary, and the patient has remained quite well and has gained much weight.

CASE 7.—The patient, a woman, aged 84 years, seen on July 6th, 1908, with Dr. H. Sharman, had had a few weeks previously slight left hemiplegia, since when cystitis had slowly developed. *Bacillus coli communis* was isolated from the urine and a vaccine was prepared. Three doses of vaccine from her own *Bacillus coli communis* were given—viz., 2,000,000 on July 9th, 5,000,000 on the 13th, and 10,000,000 on the 20th. No other treatment was adopted. By the 23rd she was well enough to get up and she made an uninterrupted recovery.

CASE 8.—The patient, an unmarried woman, aged 30 years, was admitted into Guy's Hospital for pain over the right kidney region and severe cystitis of eight months' duration. *Bacillus coli communis* was isolated from the urine, a vaccine was prepared, and three doses of 5,000,000, 5,000,000, and 10,000,000 respectively were injected at intervals of six days. The pain subsided after the first injection, and the pus in the urine disappeared entirely after the third injection. The patient was discharged cured.

CHART 1.



Case 5. Bacillus coli infection. Temperature raised for five weeks before this chart begins. The double line denotes the opsonic index.

CASE 9.—The patient, a woman, aged 40 years, seen with Dr. H. W. Armstead, had been first seen by one of us in 1907 for left renal calculus. This had so destroyed the kidney that on consultation with Mr. A. A. Bowlby it was found necessary to remove the whole organ. The patient improved much after operation, but some time subsequently she began to suffer from recurrent attacks of pain in the right kidney, associated with pyrexia. She was seen on Feb. 18th, 1909, for these symptoms. There was no pus in the urine, but it contained large numbers of *Bacillus coli communis*, whilst the index to the organism was 0·6. She has been repeatedly vaccinated with large doses of a stock vaccine and small doses of a vaccine from her own bacilli, but without any marked improvement. She refuses to be x rayed and will not entertain the idea of another operation.

CASE 10.—A man, aged 50 years, was admitted for severe aortic and mitral disease. He also suffered from retention of urine due to stricture. For this catheters had been used, and he had cystitis. *Bacillus coli communis* was isolated from the urine. Two doses of 5,000,000 of vaccine prepared from this bacillus were given at intervals of seven days. There was no improvement in the cystitis and he died from his heart disease six days after the last injection.

B. *Alimentary System.*

CASE 11.—The patient, a married woman, aged 38 years, seen with Dr. C. S. Pantin on March 18th, 1908, had had every three weeks for the last eight months attacks lasting three days and consisting of nausea, heartburn, and a severe feeling of illness with shivering and slight rise of temperature which quite incapacitated her. During an attack she was always very constipated. Since the attacks began she had lost much flesh. She had seen several medical men and duodenal ulcer and atonic dilatation of the stomach had both been diagnosed at different times, but no benefit followed treatment for these conditions. It was found that washings of the stomach contained numbers of *Bacillus coli communis* and no other organisms. From her own *Bacillus coli communis* a vaccine was prepared. It was administered at intervals of about 12 days in doses gradually increasing from 5,000,000 to 50,000,000 until Sept. 7th, 1908, when she was seen again. Her weight had increased from 7 stones 9 pounds to 8 stones 10½ pounds. She looked so well that she was hardly recognisable. She had a good appetite and she felt well. Her attacks were now very slight and infrequent. A washing from the stomach revealed the presence of *Bacillus coli communis*, but only in very small numbers. She was seen again on April 19th, 1909. She then looked well, had maintained her weight, and had had no further attacks, but she suffered, as she had for many years, from some discomfort due to a right floating kidney.

CASE 12.—The patient, a boy, aged 12 years, seen on Oct. 17th, 1908, with Dr. James Smith, had suffered from ulcerative colitis for four years, passing blood and mucus and having pyrexia, pain, and tenderness. No treatment had done any permanent good. *Bacillus coli communis* was isolated from the fæces. The patient was vaccinated with a vaccine prepared from this; he had doses varying from 5,000,000 to 50,000,000 at average intervals of a week for three months. At the same time he was given two pints of soured milk prepared with lacto-bacilline and small doses of cyllin three times a day. The improvement was immediate and rapid. An examination on Jan. 11th last showed that the atypical *Bacillus coli communis* previously found had now disappeared from the fæces. The boy is now (May, 1909) perfectly well and has been so for many months.

CASE 13.—The patient, a male, aged 30 years, seen on Nov. 6th, 1907, with Dr. W. W. Shackleton, had had for five weeks severe diarrhœa with much blood. He was very blanched. He was treated with light diet, and astringent injections were thrown high up into the large bowel. He got much better, but in March, 1908, the old symptoms returned and continued until July 9th, when he was seen again. An examination with the sigmoidoscope showed the whole mucous membrane to be intensely injected. A *Bacillus coli communis* was isolated from the fæces and a vaccine was prepared. A dose of 5,000,000 was given on July 18th, 5,000,000 on the 21st, 10,000,000 on the 31st, and 5,000,000 on August 18th. The patient then discontinued the treatment, his symptoms being improved, but they returned in October. Four doses were then given at fortnightly intervals, the patient again recovered, and when last heard of (May, 1909) was quite well.

CASE 14.—The patient, a male, aged 17 years, seen on May 16th, 1908, with Sir William Allchin and Dr. E. H. Lendon, had had severe ulcerative colitis for many months, passing mucus and much blood. He was very ill and was confined to bed. *Bacillus coli communis* was isolated from the fæces and a vaccine was prepared. He was given small initial doses, rapidly increased to 50,000,000, at fortnightly intervals. He gradually improved. The vaccine treatment was continued until last March, although in February he was well, the diarrhœa and passage of blood and mucus having ceased for a long while, he had gained weight, and was able to go to his work. He is now (May, 1909) perfectly well.

C. *Empyemata and Subdiaphragmatic Abscesses.*

CASE 15.—The patient, a tall man, seen with Dr. J. H. E. Brock and Dr. F. K. Holman, who met him at Tilbury Docks on his arrival from India, was a mere skeleton, weighing 5½ stones, and was so ill and weak that it was doubtful if he would reach his home at Hampstead alive. I (W. H. W.) saw him a day or two afterwards; he had a hectic temperature, was coughing up considerably over a pint of blood and pus like anchovy paste in the 24 hours, and his pulse was feeble and rapid. I was asked to decide whether or not the abscess should be drained, and I gave it as my opinion that the patient was so ill that he stood a better chance of recovery without than with a severe operation. In coming to this opinion I was influenced not only by his extreme weakness but also by the fact that examination did not give any clue as to the seat of the abscess, and therefore it might have been a tedious operation to find it, and the amount of blood in the expectoration suggested that incising the abscess might lead to serious hæmorrhage. We accordingly put the patient by a wide-open window and fed him up. Slowly his temperature fell, the expectoration diminished, and he gained weight. After about a couple of months he was able to travel and spent some months continuing the open-air cure in various seaside places in Devon and Cornwall. Six months after he landed in England he was unrecognisable; he had doubled his weight, but the expectoration was still about four ounces a day of pus like anchovy paste. This was examined and was found to contain *Streptococcus pyogenes longus*. We prepared a vaccine, and on Feb 15th a dose of 10,000,000 was given, on the 19th one of 50,000,000, on March 7th one of 50,000,000, and on the 27th one of 100,000,000, the dosage being checked by observations of the opsonic index. Under this treatment the expectoration ceased. The patient when last seen, a year after his arrival in England, had, so far as could be made out, nothing the matter with him. There was no expectoration. His weight was 12½ stones—that is, 7 stones more than on arrival; he looked perfectly well and could walk up hills with ease. An examination of the chest with the x rays, made by Dr. A. C. Jordan, showed that the completeness of the cure was remarkable. The right lung showed no evidence of having had immense quantities of pus (the patient calculated it was 15 gallons since his arrival in England) coughed through it. The right wing of the diaphragm was two inches higher than the left, and its excursion, though excellent, was only half that of the left.

CASE 16.—The patient, an old man suffering from mental disorder, seen with Mr. R. W. Prentice, had had pneumonia four months previously. Since then he had had a hectic temperature and had been coughing up pus; he had physical signs at the right base. He would not hear of any operation, and, considering his age and his mental condition, we were not sorry. We cultivated *Streptococcus lanceolatus* from the expectoration and prepared a vaccine. In six weeks two injections of 5,000,000, three of 10,000,000, and one of 50,000,000 were given. He improved greatly under this treatment; his expectoration ceased, his temperature became normal, and he gained weight. When heard of nine months after he was first seen he remained well.

CASE 17.—The patient, a man, aged 60 years, seen in consultation with Mr. W. Arbuthnot Lane, was short-circuited by him for a duodenal ulcer on Dec. 26th, 1908. Two days after the operation he vomited much blood, apparently from the ulcer; some got down into his lungs. Signs of pneumonia appeared at the base of the left lung. He coughed up some pus soon after. His temperature remained raised and he coughed up pus during the last three weeks of January. On Jan. 29th *Staphylococcus aureus* and *Streptococcus longus* were found in the expectoration, and a vaccine was made from each. On Feb. 5th he received a dose of 5,000,000 streptococci, and on the 8th 5,000,000 streptococci and 10,000,000 staphylococci. He then went to Bournemouth, under the care of Dr. G. Muspratt, and on Feb. 13th had 10,000,000 streptococci and on the 16th 25,000,000 staphylococci. Directly the vaccine treatment was commenced he began to improve. His temperature slowly fell, his expectoration quickly ceased, and he was soon able to walk about. He is now (May, 1909) quite well and hard at work.

CASE 18.—The patient, a female, aged 35 years, had (following a gastric ulcer) a subdiaphragmatic abscess which was drained. *Streptococcus longus* was cultivated from the pus, a vaccine was prepared, the patient had two injections of 5,000,000, and did uninterruptedly well.

CASE 19.—The patient, a female, aged 21 years, was admitted to hospital for perforated gastric ulcer. An operation was performe[illegible] of a subdiaphrag[illegible] and a few hours [illegible] she vomited a quantity of pus. Her temperature came down but soon began to go up again, and pus was discharged by the bowel. From this the *Streptococcus longus* was isolated. A vaccine was prepared from it. After three doses of 5,000,000 each the temperature became normal and the patient was discharged cured.

CASE 20.—The patient, a female, aged 34 years, was admitted to hospital on Sept. 30th, 1908, for expectoration of pus. She had had pneumonia a month previously. Physical signs and the x rays revealed an empyema in the right chest in front, extending from the second to the fourth ribs. From the pus she expectorated *Bacillus coli communis*, *Staphylococcus aureus* and the pneumococcus were isolated. Her opsonic index to the colon bacillus was 0·43, to the staphylococcus 1·024, and to the pneumococcus 2·42. Vaccines were prepared from all three, but as the index was normal to the staphylococcus and raised for the pneumococcus the *Bacillus coli communis* vaccine was the only one used. Four doses—viz., 2,000,000, 8,000,000, 20,000,000, and 25,000,000—were given at intervals of a week to ten days. The temperature had been considerably raised for some weeks, but after the first injection it began to fall. After the third it was normal and remained so till her discharge. The expectoration entirely ceased and she gained 2 stones in weight. The index to the staphylococcus and pneumococcus was taken several times and remained constant; the index to the colon bacillus was raised as a result of the injections. The physical signs improved and an x ray picture taken before her discharge showed great shrinkage of the cavity of the empyema. During most of her stay in the hospital she was on the open-air balcony day and night.

CASE 21.—The patient, a boy, aged nine years, was admitted to hospital for double empyema following double pneumonia. The right empyema was opened on Feb. 6th and the left, after two aspirations, on March 9th. A vaccine was prepared from the pneumococcus present in the pus, and two doses of 5,000,000 and two of 10,000,000 were administered at intervals of seven days. The boy made an uninterrupted and rapid recovery, gained much in weight, and was discharged cured with the wounds perfectly healed.

CASE 22.—The patient, a man aged 39 years, was operated on early in Septemb[illegible] the right side. Two pins of pus [illegible] to be doing well and the woun[illegible] of September the temperature began to rise and continued hectic until Nov. 2nd, when he was first seen by us. The x rays and physical signs showed an empyema near the spine at the eighth rib on the right side. Leucocytosis 25,000. Sir Alfred Fripp drained this empyema, letting out a few ounces of pus on Dec. 15th. *Staphylococcus aureus* and *Bacillus coli communis* were obtained from the pus. V[illegible] of each were prepared and injections varying from [illegible] to [illegible]als of a week for three months. Although the patient went to the seaside he has not improved much; there is still some discharge from the wound now (May, 1909), he has only gained a little weight, but his temperature is consistently lower although not normal. He is pale and anæmic. There are no tubercle bacilli in the sputum.

D. *Miscellaneous.*

CASE 23.—The patient, a female, seen with Dr. John Wood, had suffered for a long while from furunculosis, many boils appearing in various parts of the body. A *Staphylococcus aureus* was isolated from one of the boils. A vaccine was prepared and doses of from 50,000,000 to 100,000,000 were administered. The boils became fewer and less severe, but the improvement was not great, therefore three months after the treatment began a dose of 50,000,000 was followed three days later by a dose of 100,000,000. This produced a rise in the opsonic index to 2·5, accompanied by a rapid disappearance of the last of the boils and striking general improvement in her health.

C[illegible] years, was seen with Dr [illegible] consultation with a su[illegible]mental hernia. His temperature was raised and the swelling was very tender. No organisms could be isolated from the blood, and as it was not deemed advisable to operate the patient's opsonic index to several micro-organisms was estimated, and as that to staphylococcus was low a stock vaccine of *Staphylococcus aureus* was injected. Doses of 5,000,000 and 10,000,000 were given in June, and in 18 days his temperature became normal, the swelling and tenderness had quite disappeared, and the patient got completely well.

CASE 25.—The patient, a female, aged 45 years, seen with Dr. N. J. McCaskie for severe osteo-arthritis affecting nearly every joint in her body and rendering her almost helpless, had over the sacrum a sinus which was several inches [illegible] It had resulted from pressure [illegible] The pus was found to contain [illegible] opsonic index to this organism varied between 0·5 and 2·0. A vaccine was prepared. Five injections of it were given in doses of from 5,000,000 to 50,000,000 at intervals of about a week. The sinus was syringed out with peroxide, the pus gradually ceased to be discharged, and the sore improved in every way.

CASE 26.—The patient, a married woman, aged 27 years, was confined on April 11th, and was first seen by us on the 25th for general septicæmia and septic pneumonia. Cultivations from the vaginal discharge and also from the sputum showed the presence of *Bacillus coli communis* and pneumo[illegible] appeared to be dying. Fourteen days after the first injection the temperature had become normal.

CASE 27.—The patient, a married woman, aged 30 years, was confined on May 22nd. She had a rigor with a temperature of 104° F. on the 25th. Thereafter the temperature fluctuated between 99° and 104° with frequent rigors until first seen on June 23rd when acute nephritis with bloody urine was present. A catheter specimen of urine grew *Staphylococcus aureus* only, and as the index to that organism was only 0·35 two doses of a vaccine prepared from this particular strain were injected. The index rose to 1·5, but the clinical condition remained unaltered. In the meantime *Bacillus coli communis* had been isolated from the vaginal discharge and a vaccine prepared. On July 2nd and 5th 5,000,000, on the 7th 2,000,000, and on the 10th 10,000,000 of coli vaccine were injected. The response was immediate and by July 12th the temperature had returned to normal, and the patient made an uninterrupted recovery and now a year since remains in excellent health.

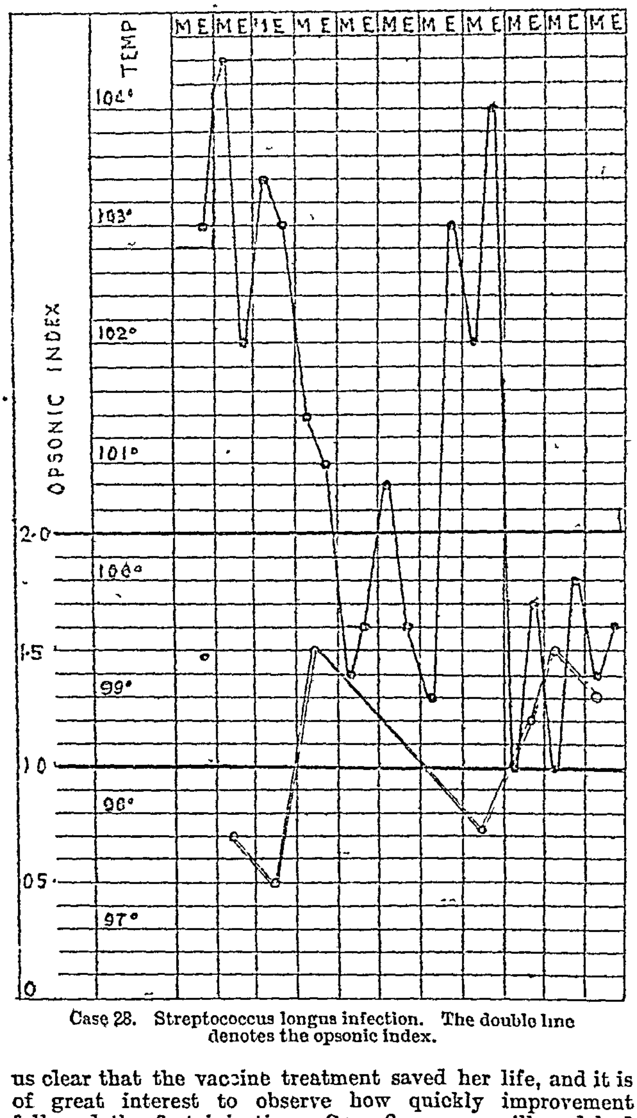
CASE 28.—The patient was a married woman, aged 20 years. This was a severe case of puerperal septicæmia. She was confined on Dec. 7th. She had a rigor on the 9th. On the following day the uterus was cleared out under an anæsthetic. On the next day large numbers of streptococci were found in the blood. Antistreptococcic serum was administered but proved useless. A vaccine was therefore [illegible] of the [illegible] at the [illegible] 100° F. [illegible]cci had [illegible]fection now remaining was a definite area of parametritis in the right fornix. Three days later the temperature again rose, and there were definite signs of septic pneumonia; no pus could be detected; the patient's strength gradually failed and she died. (See Chart 2.)

CASE 29.—The patient, a muscular young man, aged 27 years, had suffered for many years from acne pustulosa, which when he was first seen in May, 1903, completely covered the chest and neck. The face was but little affected. *Staphylococcus albus* was isolated from the pustules and a vaccine was prepared from it. During the next two months six doses of vaccine, commencing with 200,000,000 and gradually increasing to 1,000,000,000 were administered. The response to these injections was most striking, and when the patient left England in the beginning of July the chest was completely clear, the back practically clear, and all of the scar tissues remaining from previous attacks were clearly undergoing absorption.

Summarising Remarks.

It will be seen that the first four of the cases of disease of the genito-urinary system were examples of gonorrhœal arthritis, and when we remember how intractable this complaint usually is it will, we are sure, be conceded that our cases did exceedingly well with vaccine treatment The benefit which followed was so rapid that it was difficult to doubt that it was due to the vaccine. In the remaining six cases of genito-urinary infection the *Bacillus coli communis* was found in the urine. In Case 5 the patient was desperately ill when seen, and had been ill so long that it appeared to us clear that the vaccine treatment saved her life, and it is of great interest to observe how quickly improvement followed the first injection. Case 6 was very ill, and had had considerable pyrexia for over three weeks; yet two days after the first injection of coli vaccine the temperature was normal. He was treated with vaccines prepared from both micro-organisms found in his urine, but the *Bacillus coli communis* was probably the more active for harm, for it was after the injection of this that the temperature at once fell. Case 7 was a mild case of cystitis, but it is of interest that she benefited in spite of her extreme age. Case 8 did extremely well in spite of the long duration of the cystitis. In Cases 9 and 10 the vaccine treatment appeared to do no good. Why this was so in Case 9 is not quite clear, but it is to be noted that although her urine contained enormous quantities of the colon bacillus there was no pus, so that she can hardly be said to have had cystitis or pyelitis in the ordinary sense of the terms. Case 10 was so ill from his heart disease that he died before any conclusions could be drawn as to the efficacy of the treatment. Therefore out of ten genito-urinary cases in the four due to the gonococcus the improvement was rapid after vaccine treatment, and of six in which *Bacillus coli communis* was the cause of the symptoms from which the patient suffered four did extremely well, and in two cases (viz., 5 and 6) the treatment in our opinion saved the patient's life.

CHART 2.



Case 28. Streptococcus longus infection. The double line denotes the opsonic index.

Turning next to the alimentary cases, Case 11, in which the severe attacks of dyspepsia accompanied by fever were associated with and apparently due to *Bacillus coli communis* in the stomach, was very remarkable. Although an occasional colon bacillus may be found in stomach contents, yet in this patient a loopful of the stomach washing contained millions of *Bacillus coli communis* in pure culture, and it would appear that this case is an example of a hitherto unrecorded cause of severe dyspepsia. We may mention that we sought for these bacilli in another case of unusual dyspepsia, but without finding them. That they were the cause of the dyspepsia in Case 11 appears extremely likely from the fact that as the patient improved under the vaccine treatment these bacilli almost completely disappeared from the stomach contents, and that this treatment helped her very considerably appears plain; no previous treatment had benefited her at all. The remaining three gastro-intestinal cases were all examples of ulcerative colitis, in which *Bacillus coli communis* was found in the fæces. Whatever may have been the original cause of the ulcerative colitis, that this bacillus was, when we saw the patients, the actual cause of the chronic inflammation of the large bowel is highly probable, for in each case the patient's blood contained specific agglutinins, easily demonstrated in high dilutions, against the particular *Bacillus coli communis* which we recovered from the fæces and utilised in the preparation of each vaccine. Moreover, in each case the opsonic index to the *Bacillus coli communis* recovered from the fæces showed remarkable variations from day to day, ranging from 0·5 to 2·5. These three cases encourage us to hope that in the future much good may follow the treatment of this intractable disease by vaccines, especially if combined with milk soured with lacto-bacilline, and perhaps the administration of cyllin.

Eight cases fall under the heading of empyemata and subdiaphragmatic abscesses, and we are well aware that both these disorders often recover without vaccines, but in Case 15 the diminution of the expectoration, which had lasted many months, was so prompt after the giving of vaccines that it appeared to be due to them. The same was true of Cases 16 and 17, 19 and 20, and our impression derived from these eight cases is that the healing of these abscesses, usually so tedious, can often be accelerated by the administration of the appropriate vaccine. The only case in which it appeared to do no good was Case 22.

Among the miscellaneous cases only Nos. 26 and 27 call for comment. No. 26 had very severe puerperal septicæmia with a large amount of septic pneumonia. She was so near death's door before the vaccine treatment was commenced that our strong impression is that it saved her life, and the same is true of No. 27; until the vaccine treatment was adopted her temperature had been raised for six weeks and she had remained consistently very ill; after vaccination the temperature fell and she improved in every way. In all the cases recorded in this paper, unless otherwise stated, the vaccine treatment was the only special treatment adopted.

We have given brief details of each case occurring since Jan. 1st, 1908, in which we have employed vaccines, recording failures as well as successes, in order that those who are present may form their own conclusions. For our own part, we believe that in not one of these 29 cases did the vaccines do any harm, and in the great majority it appeared to us that distinct benefit followed from them; in some, indeed, they, in our opinion, saved the patient's life.

INCORPORATED INSTITUTE OF HYGIENE.—A conference on "The Medical Inspection and Treatment of School Children" will be held at the Institute of Hygiene on June 21st. It is intended specially to consider the problem of "How to deal with defective children," and it is stated that a number of prominent medical men have arranged to take part in the discussion. Sir William H Bennett, K C.V.O., will preside.

EXPERIMENTAL EVIDENCE OF THE INFECTIVE ORIGIN OF CARCINOMA

AND OF THE TRANSMISSIBILITY OF THE DISEASE FROM THE HUMAN SUBJECT TO THE MOUSE.

By W. FORD ROBERTSON, M.D. EDIN.

MANY experiments have been made with the object of ascertaining whether carcinoma can be transferred from the human subject to the lower animals. The general opinion is that these experiments have failed to furnish any positive evidence, although there are some records of positive results that the observers themselves certainly believed to be genuine. In 1900 Gaylord[1] asserted that in six animals (rabbits and guinea-pigs) he had succeeded in producing carcinomatous lesions by the injection of carcinomatous material from the human subject, and two years later[2] he recorded the production of multiple carcinomatous nodules in the liver of a dog as the result of the injection of peritoneal fluid from a case of malignant peritonitis. In 1902 Mayet[3] stated that in 53 white rats injected with glycerine extract of a cancer of the human breast he had obtained four lesions that were certainly cancerous and eight that were probably of the same nature.

It is possible that past failures to obtain satisfactory evidence of the transmissibility of carcinoma, apart from mere grafting of tumours upon an animal of the same species, have been due simply to the fact that the methods employed were not suitable. It may, for example, be essential to introduce the supposed protozoan organisms at a particular phase in their life cycle and in large numbers. This, in fact, is the hypothesis that I endeavoured to test in carrying out the experiments, some of the results of which I wish to record briefly in this paper.

The material used for the purposes of the experiments was kindly supplied to me by Dr. William Russell in August, 1907. It consisted of about 300 cubic centimetres of fluid from the pleural cavity of a woman suffering from malignant pleurisy, secondary to mammary carcinoma, and of about [illegible] a [illegible] ed [illegible]

The experiments were carried out upon mice and have been fully controlled by the observation of a much larger number of animals of the same stock kept under similar conditions. During the past three years this stock has consisted of from 60 to 80 mice, among which there has always been a considerable proportion of aged animals. None of these mice have developed external tumours. I have examined over 60 mice that have either died in the course of being subjected to ordinary virulence tests, or have been found dead in their cages, and I have not been able to observe any internal carcinomatous lesions. Among these animals a sufficient number to form a satisfactory control series were of ages not less than those of the mice upon which the experiments were made. Three separate experiments were carried out.

Experiment 1.—Six mice were each injected in the abdominal wall with about one cubic centimetre of the fluid (incubated for about two months) from the case of malignant peritonitis. The results of the experiment were negative as regards the development of tumours.

Experiment 2.—Five mice (a mother and four suckling young) were fed on one occasion with about five cubic centimetres of similar fluid from the case of malignant peritonitis. The results of this experiment were also negative.

Experiment 3.—30 mice of ages ranging from three to 12 months were fed with about 20 cubic centimetres of the fluid from the pleural cavity of the case of malignant pleurisy. This fluid had been incubated at 37° C. for seven weeks. On the following day they were similarly given fluid (incubated for about nine weeks) from the case of malignant peritonitis. In the course of the succeeding five to 14 months seven of these mice developed carcinomatous tumours—namely, three of the mammary gland, two of the lung, one of the testicle, and one of the uterus. In addition to these tumours there were, in two other cases, fatal lesions of the stomach and liver, which were probably, but not certainly, malignant growths. Another mouse, one of 13 young born in the cages in the course of this experiment, also developed a large carcinoma of the breast which caused its death.

Mouse No. 1.—A small tumour was observed in the flank five months after the feeding. It grew rapidly and the animal died one month later. The tumour measured 23 millimetres in diameter. It has the structure of an adeno-carcinoma (Fig. 1).

Mouse No. 2.—A tumour was observed in the left breast ten months after the feeding. It rapidly increased in size and the animal died two months later. The tumour was 25 millimetres in diameter. It has also the structure of an adeno-carcinoma but is denser than the preceding (Fig. 2).

Mouse No. 3.—The animal died a little more than a year after the commencement of the experiment. Some weeks previously a small tumour of the breast was observed. On the death of the animal this tumour measured 12 millimetres in diameter. It also has the structure of an adeno-carcinoma (Fig. 3).

Mouse No. 4.—The animal died about nine months after the commencement of the experiment. On examination there was found a firm whitish nodule projecting slightly from the anterior surface of the right lung. This nodule measured 4·5 millimetres in diameter. It is composed of large epithelial cells (Fig. 4), which at the margin can be seen to be invading the neighbouring lung tissue.

Mouse No. 5.—This mouse died nearly 14 months after the feeding. A dense whitish nodule, measuring 6·5 millimetres in diameter, was found in the right lung. This growth consists of large epithelial cells arranged for the most part in columns (Fig. 5). It presents evidence of rapidly infiltrating the neighbouring lung tissue.

Mouse No. 6.—The animal died 11 months after the commencement of the experiment. It was found to have a large solid tumour of the right testicle, measuring 14 millimetres in diameter. This had evidently pressed upon the large intestine and caused obstruction. The tumour consists throughout of large epithelial cells (Fig. 6).

Mouse No. 7.—This animal was killed ten weeks after the commencement of the experiment when it seemed moribund. For some days previously it had been observed to be ill and the abdomen was much swollen. On post-mortem examination there was found to be very great general increase of the subperitoneal fat. Both horns of the uterus were much thickened, being at least 12 times the diameter of the normal organ. On microscopical examination the muscular and submucous coats are seen to be greatly thickened. The latter is extended in the form of numerous polypoid projections covered by proliferating surface epithelium. Throughout the submucosa there are larger or smaller masses of epithelial cells, for the most part presenting a glandular arrangement. Some may be inclined to regard the lesion in this case as simply an endometritis. For my own part, on account of the irregularity and evident rapidity of the epithelial proliferation, the occurrence of local invasion of the muscular coat, and the absence of inflammatory exudation, I am satisfied that the condition is carcinomatous.

The mammary tumour which developed in the young mouse born in one of the cages some months after the commencement of this experiment is 15 millimetres in diameter, and has the histological characters of an adeno-carcinoma. This tumour is not included in the positive cases.

In this experiment seven out of 30 mice developed carcinomatous tumours. As the control animals have not shown any similar tumours, and as the only difference in the treatment of the two series was that the 30 mice were fed with incubated carcinomatous material from the human subject, I infer that the epithelial tumours were determined by some agent contained in this carcinomatous material. As none of the 11 animals injected or fed with the fluid from the case of malignant peritonitis developed carcinomatous growths, it seems probable that this agent was contained in the fluid from the case of malignant pleurisy. It was certainly unfortunate that in the third experiment the animals were fed with material from both cases of human

carcinoma. But this circumstance cannot to any great extent detract from the significance of the results. These three experiments were meant to be merely of a preliminary nature. It was my intention to make other observations with similar material incubated for various periods. But until quite recently I have been unable to obtain any further supply of carcinomatous fluid. Many more experiments of a similar kind are needed, and it is largely with the purpose of commending such work to others who have the necessary time and facilities, which I have not, that these initial observations are now recorded. There is probably for the production of tumours an optimum period of incubation of the carcinomatous fluid, and this will, I think, be found to be shorter than the time in my experiments.

On the ground of the experimental results that I have recorded it could, I think with good reason, be contended that the pathogenic agent transferred from the human subject to the mouse was not merely a chemical substance but must have been a living virus. This contention has, however, a still stronger support. It is borne out by abundant evidence of a direct character. From one of the mammary tumours occurring in these mice I made several cultures upon non-nutrient agar-gelatin, similar to those described some years ago in a paper by Dr. Henry Wade and myself.[4] These cultures have been studied in section by means of the ammonio-silver process by Dr. M. O. W. Young, who has been able to demonstrate in them certain morphologically characteristic forms identical with those already observed by us in malignant tumours from the human subject and more recently in one of the original Jensen mouse tumours. Some of these forms have also been demonstrated in these experimental tumours, as well as in a mammary tumour produced in a previously healthy mouse by inoculation of one of these growths. Our more recent observations, some of the results of which were demonstrated on Feb. 26th at a meeting of the Edinburgh branch of the British Medical Association, lead to the conclusion that a group of protozoan organisms, to be classed among the mycetozoa and including very numerous pathogenic species, is associated with tumour growth, just as very numerous pathogenic species of schizomycetes are associated with inflammation. The main phases in a complicated life cycle have now been demonstrated in sections of tumours, in sections of agar cultures from tumours, and in films of the centrifuge deposit from fluid from cases of malignant pleurisy secondary to carcinoma of the breast. The phases recognised include forms with flagella, sporoblasts and their residua, nucleated forms, some of which have been observed in mitosis, and certain other remarkable bodies of characteristic appearance which almost certainly represent gametes.

Edinburgh.

A NOTE ON

THE RECURRENCE OF VESICAL CALCULI AFTER REMOVAL IN A SERIES OF 160 OPERATIONS.

BY F. A. SOUTHAM, M B. OXON., F.R.C.S. ENG.,
SURGEON TO THE MANCHESTER ROYAL INFIRMARY; PROFESSOR OF CLINICAL SURGERY, UNIVERSITY OF MANCHESTER.

HAVING recently performed lithotrity (or litholapaxy, as the operation is now termed) for the sixth time within a period of 16 years upon the same patient, a male, now aged 76 years, the frequent recurrence of the calculi in the bladder naturally suggests the question whether their presence there has been due to the descent of more calculi from the kidney or to small fragments left in the bladder after operation, either of which may form the nuclei of fresh vesical calculi.

In this case the patient had undergone the operation of perineal (lateral) lithotomy for the removal of a stone 15 years before he came under my care for the first crushing [illegible] from [illegible] per- [illegible] als of one year, ten years, two years, three years, and one year, the calculi consisting of uric acid, and in each instance being considerably under an inch in diameter. As the first crushing operation occurred 15 years after a calculus had been removed by lithotomy, there must on the first recurrence have certainly been a descent of a fresh calculus from the kidney; and, as an interval of ten years elapsed between the second and third crushings, it is not probable that a fragment left after the second crushing operation formed the nucleus of the stone removed so many years subsequently. It would appear, therefore, that provided the bladder is thoroughly cleared of the fragments, as is now possible owing to the improvements during recent years in the technique of the crushing operation, a recurrence after lithotrity is generally due to the descent of a fresh calculus from the kidney.

The tendency to a recurring formation of calculi in the kidney was well illustrated in the case of a patient, aged 20 years, upon whom I performed lithotrity some years ago, for he brought with him a collection of 41 uric acid calculi, some measuring a quarter of an inch in diameter, which he had from time to time previously passed per urethram. In six patients I have twice performed lithotomy, and in one of these the calculus again recurred, necessitating a further operation. In two other patients, after removing calculi from the bladder I subsequently performed nephro-lithotomy, on [illegible] the [illegible] ca[illegible] after a cutting as after a crushing operation; in fact, in my experience it has been practically the same—viz., 7 per cent.

Summary of 160 Operations for Calculus Vesicæ.

—	Nature of operation	No. of operations.	No. of patients.	No. of patients in whom calculi recurred.	Percentage of recurrences.
Males	Lithotrity	61	56	4	7·1
	Lithotomy	89	83	6	7·2
Females	Vaginal lithotomy ...	1	1	0	—
	Dilatation of urethra	9	9	0	—

In ten male patients the calculi recurred after operation—viz., in four after lithotrity and in six after lithotomy (17 lateral and 72 suprapubic operations). One patient (already mentioned) was operated upon six times, another patient four times, and the remaining patients each twice. The longest interval between any two successive operations was 19 years, this period intervening between the operations of lateral and suprapubic lithotomy performed upon a patient aged 53 years at the first operation, and 72 years at the second. Of the patients in whom a recurrence took place, one was in his fiftieth year and the others were all over 56 years of age when the first operation was performed; four patients were aged respectively 72, 72, 76, and 79 years.

No instance of recurrence was met with in younger subjects, of whom 27 were under ten years of age, and of these 14 were treated by lithotrity.

From a consideration of the results in my series of cases, it would therefore appear that a recurrence of calculi after operation is relatively not more common after lithotrity than after lithotomy, and when it does take place it is in both instances probably due to the descent of a fresh calculus from the kidney and its retention in the bladder. The percentage of recurrences after lithotrity given in the above summary—viz, 7·1 per cent.—is somewhat less than that of other surgeons. Sir H. Thompson[1] met with a recurrence in 75 patients out of a total of 600 cases = 12·5 per cent.; Cadge[2] in 18 patients out of a total of 133 cases = 13·6 per cent.; and R. Harrison[3] in 23 patients out of a total of 101 cases = 22·7 per cent. It is interesting to note that Freyer[4] in his Indian experience of lithotrity met with a recurrence in ten patients only in a series of 610 operations, which gives a much lower percentage of recurrences—viz, 1·6 per cent.

[4] The Modern Treatment of Stone in the [illegible] second edition, p. 56.

The more satisfactory results of lithotrity at the present day, as compared with those in the early years of the operation, are no doubt mainly owing to the fact that we now employ larger evacuating catheters, which enable us to remove the broken-up fragments from the bladder much more thoroughly than was formerly the custom.

Manchester.

PUSTULE SIMULATING ANTHRAX DUE TO ORGANISMS OF THE PROTEUS GROUP.

BY THOMAS ORR, M.D., B.SC. (PUB. HEALTH) GLASG.,
BACTERIOLOGIST AND ASSISTANT COUNTY MEDICAL OFFICER, WEST RIDING OF YORKSHIRE.

So much doubt exists as to the possibility of organisms of the proteus group, in the absence of other organisms, causing pathogenic lesions in man that the following case is worth recording. The case is interesting not only on account of its rarity but also because the lesion presented characteristics indistinguishable from malignant pustule, for which it was mistaken and as such treated.

A butcher, 45 years of age, first noticed a small pimple on the back of his left thumb about the middle of the metacarpal bone. This slowly increased in size but showed no signs of suppurating. There was little or no pain felt and he did not complain of feverishness or of being ill. As little discomfort was experienced, he did not seek medical advice until about a fortnight after its first appearance and until it had much increased in size. When examined by Dr. William Craik, Thurnscoe, there was found a hard raised swelling of about the size of a shilling over the area mentioned. The top of the swelling was depressed or crateriform and was dark and necrotic in appearance. At the margin of the necrotic area was distinct vesiculation and the skin around for about a quarter of an inch was dusky red with a bluish tinge. There was no evidence of pus formation. The appearances were uncommon and at once suggested malignant pustule. On the day when seen the sore was treated by injecting a solution of carbolic acid into the centre and periphery. On the next day the necrotic part had extended and the skin was inflamed to a greater extent. A crucial incision was therefore made and salicylic acid was dusted into the wound. On the following day it was thought advisable to excise the pustule on the assumption that it was due to the anthrax bacillus. Before excision a little of the serum exuding from the previous day's incision was collected in a glass tube for bacteriological examination. Within ten days after excision a small secondary papule developed at the margin of the wound. This was incised and dusted with salicylic acid. In a few days the inflammation began to subside and the wound slowly healed.

Bacteriological Examination.

1. *Serum from incised wound.*—Films made from the serum and stained failed to show any organisms. A loopful spread on an agar plate gave a few white colonies which were found to be of *Staphylococcus albus*. The presence of these organisms was probably due to contamination from the skin owing to want of aseptic precautions in collection.

2. *Excised pustule.*—The pustule on excision was put into sterile distilled water and next day examined. Films made from the fluid exuding from the freshly cut surface of the tissue and stained showed the presence of small bacilli with rounded ends. These were found both singly and in small groups and retained the stain by Gram's method. The surface of the tissue was seared with a hot iron and incised with a sterile knife. The fluid exuding from the cut surface was spread on nutrient agar plates. After 24 hours' incubation at 37° C. there were found numerous small colonies of two different types. Both types of colonies occurred in about equal numbers and were found to be composed of Gram-staining bacilli to be described later. Sections of the tumour examined microscopically showed areas of necrosis surrounded by areas of leucocyte infiltration, the leucocytes being large mononuclears. In the zone between these areas of necrosis and infiltration were found many Gram-staining organisms. These were bacillary in form, irregular in size and in shape, many swollen at the ends or in the middle, and some large and spherical.

3 and 4. *Specimens from the secondary papule.*—Two sterile cotton-wool swabs were rubbed in the centre of the secondary papule and submitted for bacteriological examination. These two specimens were taken on different days. Agar plates were smeared with the swabs, and after 24 hours' incubation they showed two kinds of colonies (A and B) similar to those isolated from specimen 2. These also were found to be composed of small Gram-staining bacilli.

Thus, from specimens 2, 3, and 4 two kinds of organisms were isolated. In their morphological and biological characters they belong to the proteus group. Both organisms were very motile and non-sporing, and retained the stain by Gram's method. Both occurred as small slender rods with rounded ends, sometimes in chains. B was often arranged end to end in pairs and was slightly thicker than A. In old cultures both showed a variety of shapes; some of the bacilli presented irregular forms with swollen ends. On agar slopes the growths of both organisms were somewhat similar, being greyish-white and glistening or slimy, but A slightly more opaque than B. On agar plates A occurred as small greyish-white opaque glistening colonies with a regular margin; B showed colonies each of which had an opaque greyish-white centre and a thin transparent margin, the transparent margin being much broader than the opaque centre. A liquefied rapidly, a deep saucer-shaped hollow of liquefaction being found in the gelatine stab in 72 hours, while B liquefied much more slowly, in seven days a shallow cup of liquefaction being formed. Both produced acid and gas in glucose and saccharose but not in lactose broth. A corresponds in microscopical and cultural characters with *Proteus vulgaris* (Hauser), while B presents characteristics similar to *Proteus mirabilis* (Hauser) as described by Lehmann and Neumann. It would thus appear that the sore was caused by these two organisms belonging to the proteus group, *Proteus vulgaris* (Hauser) and *Proteus mirabilis* (Hauser).

Although such infection by these organisms is unusual, it should not be unexpected when the man's version of the origin of the sore is considered. He stated that he had got in his thumb some poisonous material from bags sent out by hide and refuse dealers. These, he says, are sometimes very dirty and bad-smelling. They are used again and again without cleaning, passing from one butcher to another. In [illegible] for collecting fat and bones [illegible] large numbers of organisms [illegible] are certain to be present.

Wakefield.

SUDDEN FAILURE OF RESPIRATION RESTORED BY ARTIFICIAL MEANS,

OCCURRING DURING THE COURSE OF AN ACUTE PNEUMONIA COMPLICATED BY COMA OF URÆMIC ORIGIN.

BY ROBERT KNOX, M.D. EDIN., M.R.C.S. ENG., L.R.C.P. LOND.,
MEDICAL OFFICER IN CHARGE OF ELECTRICAL DEPARTMENT, GREAT NORTHERN CENTRAL HOSPITAL, HOLLOWAY-ROAD, LONDON, N.,
AND
JOHN MORISON, M.B., C.M. EDIN.

THE chief points of interest in the following case are (1) the sudden failure of respiration, restored by artificial respiratory movements; and (2) the rapid progress of the fatal symptoms.

The patient was a married man aged 40 years. He gave a previous history of some bone trouble in early life which affected his left hip and knee joints and one or two ribs on the left side; probably necrosis of bone with separation and protrusion of fragments. For three days before the onset of his fatal illness he complained of headache. On the fourth day (Feb. 10th, 1909) he was seen by Dr. Morison, when he still complained of headache and sleeplessness. The temperature was 102° F., the pulse was 100 and of moderate tension, and the tongue was furred, moist, and glutinous. There was slight cough, and the respirations were increased in frequency. Examination of the chest revealed a small area of dulness at the left base, and on auscultation there were prolonged expiration and moist crepitations over the area of dulness. The urine was clear, but was not examined for albumin. At 6 A.M. on Feb. 11th the following condition was noted. The patient had a restless night, with very little sleep, and complained of severe headache. The temperature was 100° and the pulse-rate was 100. He was not at all drowsy. The urine passed during the night had been inadvertently thrown away. At 9 A.M. the patient was sleeping heavily, with an inclination to stupor, but as he had had a veronal powder (seven and a half grains) the night before little notice was taken of this. The pulse was 120 and the respirations had become more rapid. At 10 30 A.M. he was comatose; the pupils were moderately dilated, *there being neither light nor conjunctival reflex*; the respirations were laboured and over 50 per minute, and the pulse was 160, dicrotic, and the impulse sharp. There were moist sounds all over the right lung, especially at the base anteriorly. The heart showed a regular heaving apex impulse, the temperature was 106°, and the surface of the body was warm and inclined to sweat. A diagnosis of commencing pneumonia was made. The comatose condition was looked upon as being of uræmic origin, and vigorous treatment was commenced; one-thirtieth of a grain of strychnine was injected subcutaneously and oxygen was administered continuously. An ice cap was applied to the head and the surface of the body was sponged with ice-cold cloths. The temperature fell to 104° and remained at that level for some time, with a tendency to rise to 105° when sponging was relaxed. At 11.30 the respiration suddenly and unaccountably failed, the face became deeply cyanosed, and for about 20 seconds the patient remained in this condition; the pulse continued to beat vigorously, and artificial respiration was resorted to, not with any definite hope of the patient resuming breathing but more as a matter of routine and, in view of the strong cardiac action maintained for a period of seconds. After a few seconds of vigorous handling the respiration was gradually resumed and restored to its former rhythm. The temperature remained high. The patient showed no signs of improvement, so at 12 midday the median basilic vein was opened; the bleeding was not satisfactory, about 10 ounces of dark venous blood being removed. The immediate effect of the bleeding, however, was satisfactory; the patient's colour improved, his respirations became more regular and less rapid, but the coma continued. At 7 P.M. a pint and a half of blood-stained urine was removed from the bladder and when examined it was found to contain albumin in large quantity and fresh blood. The specific gravity of the urine was 1020; at this stage the respirations were about 48 and the pulse about 140. The patient continued in the same condition until about 8 P.M., when the symptoms deepened, and he gradually sank, dying at 9 o'clock on the same evening.

The case is instructive from several points of view. The rapid progress of the grave symptoms left but little time to do anything for the patient.

The question of diagnosis naturally was the most important point for immediate consideration. A patient, presumably well a few days before, is suddenly taken with an inflammatory attack, a rising temperature, rapid breathing with physical signs of pneumonia, and a rapidly advancing coma. Obviously, the pneumonia symptoms were not sufficient to account for the rapid collapse of the patient. The conditions that suggested themselves to our minds were uræmic coma, diabetic coma, or poisoning. The urine on the previous evening had been clear, no suspicion of blood being present. *Uræmic poisoning as the cause of the coma* was suggested (in addition to the blood in the urine) by the headache which had persisted for several days. The previous history of the patient, who suffered from some obscure eye troubles accompanied by headache without any obvious error of refraction, also gives support to the possibility of uræmic poisoning. It is a matter of regret that no post-mortem examination could be made in this case. The history of the case was quite unlike that of diabetic coma. The possibility of poisoning was suggested by the presence of a small bottle of chlorodyne, half emptied, in the bedroom; the condition of the pupils negatived poisoning by opium. The provisional diagnosis of pneumonia complicated by uræmic coma seems to be the most satisfactory.

The treatment resorted to undoubtedly prolonged the patient's life—oxygen relieved the cyanosis, ice reduced the temperature, and the effect of the unsatisfactory bleeding certainly supported the view that in similar and less severe cases this method of treatment is decidedly useful.

The most startling feature of the case was the sudden failure of respiration; this, in the experience of both of us, was unique. We have seen as sudden failure in anæsthesia cases, but never during the course of an acute and rapid illness such as we had to deal with. The patient was to all appearances dead when artificial respiration was resorted to, and we shall not readily forget the sudden stoppage and the slow return of respiration under artificial respiratory movements.

Obviously in such severe cases there is small chance of doing much for the patient. The experience gained in this case strengthens our hands in the consideration of future, and let us hope less grave, conditions. In view of the very stinted bleeding from the median basilic vein it might be better to open the external jugular, and so directly relieve the over-gorged central circulation. Oxygen should be used f[illegible] fresh saline solution [illegible]

A TROPICAL FORM OF ADENITIS APPARENTLY DUE TO AN AS YET UNRECOGNISED ORGANISM.

BY R. LEONARD LEY, M.B. CANTAB., M.R.C.S. ENG., L.R.C.P. LOND.

I HAVE seen recently three cases of adenitis that would come under this heading, and as I believe little is known about the disease in this country, and find no reference to it in the standard medical works or text-books, I thought the cases worth recording. What little I have learnt is from the patients themselves and from the examination of the glands from the first case. My three cases have been in soldiers who had recently served in Burma and Northern India, where apparently it is common.

CASE 1.—*The patient*, who had been home from Burma for one year, attended the out-patient department of St. Mary's Hospital, London, at the end of August, 1907, and was admitted under the care of Mr. S. Maynard Smith early in September. He gave the following history. He had noticed swellings in the groins about 18 months previously. These had gradually grown larger, as the result, he thought, of playing football. He had on admission masses of enlarged glands in both groins, of the size of a large closed fist. Some of the glands were soft and the individual glands moved fairly freely on one another and on the surrounding tissues. The skin over the glands was thinned, and in one place on the right side undermined. He denied all venereal disease and there were no signs of syphilis. There were no enlarged glands in other parts. The history was too long for malignant disease, primary or secondary, and there was no evidence of primary [illegible] the glands had all the characteristics of [illegible] removed, and [illegible] were found strongly to resemble tuberculous gland. Some of the glands were of the size of pigeons' eggs and were riddled with foci of caseous material which was of a greenish-yellow colour and was of softer consistency than that usually found in tuberculous glands. The colour, however, was the main point of difference, being very unlike the creamy-white appearance of a broken-down tuberculous gland. The glands were examined in the pathological laboratory of the hospital, and when examined microscopically the changes found were quite unlike those found in tuberculous adenitis; there were none of the characteristic tubercles with giant cells, and in spite of repeated attempts, no tubercle bacilli or any other organism could be stained. It seemed certain, however, from the microscopical findings that some organism, whose staining affinities were unknown, was present, which produced a chronic inflammation going on to necrosis in much the same way as the tubercle bacillus. It was then suggested that it might be some form of tropical disease, and on questioning the patient I discovered that such a disease existed which attacked men and animals (horses and mules), that the glands in the groin were those usually attacked, and that the animals got the disease from cracks in their hoofs from in saline. No superficial ulceration is produced at the site of the injection.

2. Glycerine extract of liver. This is not so toxic and the dose used was 15 minims of a half dilution in saline. No superficial ulceration is produced at the site of injection; the extract has the disadvantage of being particularly unstable.

3. Mixed extracts of intestinal mucosa and liver. 10 minims of mixed intestinal extract (one-half dilution) plus an equal amount of liver extract (undiluted) was toxic and lethal without producing superficial ulceration. The dose tolerated of the foregoing mixture was five minims.

4. Mixed extracts of intestinal mucosa, liver, and pancreas. This is very toxic, and the superficial ulceration produced necessitated the destruction of the animals. It was, however, found that five minims of the following mixture was tolerated: equal parts of intestinal extract (one-half dilution), liver extract (undiluted), and saline solution, plus 4 per cent. of pancreatic extract (one-half dilution); the tryptic strength of the pancreatic extract was 10 grains, and the amylolytic strength five grains to the drachm (A. and H.).

5. Splenic extract (ox). The spleen was digested in water containing 0·2 per cent. of acetic acid. The dose employed was 15 minims of one-half dilution with physiological saline solution, but no toxic or ulcerative effects were produced by the same dose of the undiluted extract.

The investigation was commenced in March, 1908, and up to the end of July it seemed to afford me some ground for encouragement. For example, in one series of nine mice, which survived, although previous treatment with intestinal extract did not prevent the tumours from appearing after inoculation, two tumours grew progressively and seven became absorbed. In another series of 16 mice two were negative to inoculation, six grew, and eight became absorbed; while in a third series of 12 mice, treated with the mixed extracts of intestine, liver, and pancreas, two were negative to inoculation, three tumours grew, and these, together with seven which were positive to inoculation, practically disappeared. No conclusion was, however, permissible from these results owing to the early death of some of the treated and untreated (control) mice in the several series. Neither was any conclusive result obtained by treatment with liver extract alone, owing to its liability to undergo decomposition.

Repetition of treatment with the mixed extracts during later months has not given the same result nor confirmed the earlier hopes. For example, in one series of 16 mice four were negative to inoculation, six growths took place and six disappeared, compared with six growths out of 12 and six disappearances in the untreated controls. As regards the growths, the slight difference in favour of the treated mice is not sufficient to demonstrate a specific action, since the tendency to spontaneous absorption was also present in the controls. As regards the negative cases and absorbed growths, in favour of the treated also, it is not possible to say whether treatment assisted natural processes or not.

In the case of tumours of generally slower growth there is no evidence that any beneficial influence has been exerted, although in such cases it is more difficult to arrive at a comparative conclusion, especially as regards retardation of growth. In other observations on rapidly growing tumours without a tendency to natural absorption the treatment did not arrest their onward progress. In one series in which splenic extract was used, while six were negative to inoculation and five growths disappeared, there seemed to be increased growth, eight progressive tumours occurring in 19 mice treated, compared with three in the 12 untreated control animals. The treated mice had a smaller average weight than the untreated; this may have been a possible factor in the result.[6]

It is too early to conclude that these results are condemnatory of the whole theory of intracellular ferment action and ferment treatment in carcinoma. They refer solely to the hypodermic method of administration or to particular combinations of the extracts employed.

Tables I. and II. present in a concise manner the whole series of observations, chiefly with the mixed extracts, on squamous celled carcinoma (mammary), adeno-carcinoma, and medullary cancer in mice. Table I. shows the results in cases in which treatment was commenced previous to inoculation and continued afterwards. The small difference in favour of the treated mice in Series A and C so shown may have some significance, but does not appear to be conclusive. Table II. shows the results in which mice were treated after inoculation, and shows that the results in these therapeutical experiments must be considered negative.

Green-street, Park-lane, W.

LABOUR OBSTRUCTED BY A FIBROID TUMOUR; CÆSAREAN SECTION; SUPRAVAGINAL HYSTERECTOMY.

BY C. E. PURSLOW, M.D. LOND., M.R.C.P. LOND.,

HONORARY OBSTETRIC OFFICER, QUEEN'S HOSPITAL, BIRMINGHAM.

I SAW this patient in consultation with Mr. J. K. Syms at her own home at 11 P.M. on Feb. 20th last. She was 39 years of age and this was her first pregnancy. There was nothing in her previous history which pointed to the existence of a fibroid tumour. Labour pains had commenced 24 hours before I saw her, and the membranes had been ruptured ten hours. Mr. Syms on being called in at once recognised that there was a tumour obstructing labour and asked me to see the case with him.

On examining the abdomen a breech presentation could be diagnosed, and it was easy to make out that the presenting part was well above the pelvic brim; nothing could be felt of the obstructing tumour by abdominal palpation. On making a vaginal examination the pelvis was found to be occupied by a hard, somewhat uneven, tumour, which could not be displaced; the os was clearly in front of the tumour, which pressed upon the posterior vaginal wall, but by the greatest effort it was not possible to reach the cervix with the examining finger, the pelvis being completely occupied by the growth. Cæsarean section was decided upon and the patient was taken to the Queen's Hospital in a cab, and at 1 A.M. I operated.

The abdomen was opened by a median incision, and the uterus was likewise incised vertically in the middle line, and child and placenta were removed. The tumour was found to be growing from the posterior wall of the uterus low down and by a broad base of attachment. Hysterectomy seemed to be the most suitable operation, and I accordingly removed the uterus and tumour by the supravaginal (or subtotal) method, the edges of the cervix were brought together by catgut, the peritoneum of the pelvic floor was united by continuous fine silk sutures, and the abdominal wall was closed in layers.

The patient made an uninterrupted recovery. She was unable to suckle the child, as no milk was secreted; artificial feeding was used, but the child made good progress and both mother and child left the hospital in excellent condition at the end of a month.

Birmingham.

A CASE OF HERNIA THROUGH THE FORAMEN OF WINSLOW.

BY WALTER H. HAW, B.A., M.R.C.S. ENG., L.S.A. LOND.,

DISTRICT SURGEON, KNYSNA, CAPE COLONY.

THE following case, which occurred in my practice recently, is perhaps in some respects unique. According to Treves,[1] "hernia into the foramen of Winslow occurs in adults, and in men more often than in women. Eight cases at least have been recorded."

A coloured boy, aged five years, was brought to my surgery at 9 A.M. on the morning of Jan. 28th in a moribund condition, and he died within half an hour while in the surgery. The history was as follows. On Jan. 15th his mother had applied to me for medicine for the boy, who had shown symptoms of worms. The powders (santonin and calomel) and medicine given had apparently been followed by good effect, for on the 27th he was running about at play and appeared all right until 7 A.M. on the 28th. At this time he was suddenly seized with abdominal pain and great tenderness, and he was brought to my surgery, as stated, at 9 A.M., his death occurring half an hour later.

---

[6] In the treated of this series a moveable lymphatic gland in the inguinal region on the side of inoculation was evident to palpation in seven (in one case bilateral) of the negative cases and absorbed growths. In the treated of Series C, No. 4, the same was noted in eight (in one case bilateral) similar cases, and in one of the untreated controls; in this series also metastasis took place, apparently in the lymphatic gland in one of the treated cases.

[1] System of Surgery, 1898 edition, vol. ii., p. 658.

At the post-mortem examination it was discovered that the cæcum, the appendix, and part of the ileum lay behind the stomach, having passed through the foramen of Winslow. Reduction was impossible until the gastro-hepatic omentum *containing the vessels, &c., passing to the liver was divided,* when the mass was easily withdrawn. A curious part of the case was that the cæcum and appendix up to the tip of the latter were tightly packed with round worms, the appendix being about the diameter of the thumb and conical in shape. 53 large worms were removed from the cæcum and appendix. The strangulated portion was naturally deeply congested and swollen, but the rest of the small intestine was not dilated, although there was some injection of the mesenteric vessels [illegible]

[illegible] re: (1) the age of the [illegible]; and (3) the fact that the condition was apparently directly brought about by the presence of the worms.

Knysna, Cape Colony.

A CASE OF ACROMEGALY.

BY E. P. CARMODY, L.R.C.P. LOND., M.R.C.S. ENG.

THE patient, a married woman, aged 33 years, was seen by me first on Dec. 19th, 1908. She complained of constant headaches, most marked over the forehead, and general *weakness, and stated that she had been in poor health for* about seven years. She had noticed enlargement of her hands and face for the last two years and had become round-shouldered. Her voice had been getting deeper and harsher. Catamenia had ceased six years ago. There were profuse sweatings at night. There was a history of rheumatic fever. Her condition was as follows. She was intelligent. She was a sallow, unhealthy-looking woman. There was enlargement of *the face, especially* the nose, *lower jaw,* and lips. The frontal region was prominent. The skin and deeper tissues all over the body were thickened but could be pinched up without difficulty. The nasal and tarsal cartilages were increased in size. The ears were leathery. The lower jaw was large, but the lower teeth met the upper teeth when the mouth was shut. The teeth were good and regular. The lips were thick and pendulous. The tongue was slightly enlarged. There was marked kyphosis in the cervico-dorsal region. The clavicles and ribs were large and unduly prominent. The lungs and heart were normal. There was marked impairment to resonance under the manubrium sterni. The thyroid gland was not enlarged, but the patient had previously been under treatment for goitre. The skin was abnormally active. The hands were increased in breadth and the fingers much thickened; the natural creases of the hand were well marked. The feet were unaffected. The larynx was large. The vision was indistinct for near objects There was slight dyspnœa. The urine had been examined on several occasions and contained no albumin nor sugar. Mentally the patient was usually melancholy. Although intelligent at times she was not clear as to her surroundings. Her memory for recent events was bad. She suffered intermittently with insomnia.

I have treated the patient with phenazone for the headaches and have given two-grain tabloids of pituitary extract three times a day for six weeks. Up to the present there is no improvement.

Tilehurst, Berks.

PROVIDENT NURSING.—A special meeting of the council of the Charity Organisation Society will be held on June 28th, at 4 30 P.M., at Denison House, Vauxhall Bridge-road, S.W., when Miss Amy Hughes of the Queen Victoria Jubilee Nurses Institute will read a paper on Provident Nursing. Sir Alfred Lyall, G.C.I.E., K.C.B., will take the chair, and the Right Rev. the Bishop of Islington will speak.

ROYAL SOCIETY OF MEDICINE.

MEDICAL SECTION.

Treatment of Typhoid Fever with an Anti-endotoxic Serum.

A MEETING of this section was held on May 25th, Dr. NORMAN MOORE being in the chair.

Professor R. T. HEWLETT read a paper on the *Treatment of Typhoid Fever* with an Anti-endotoxic Serum. He said that it was generally recognised that an anti-typhoid serum prepared by the injection of the horse with cultures of the typhoid bacillus was useless in the treatment of typhoid fever. An anti-endotoxic serum had been made by the injection of the horse with typhoid cell-juice. Such a serum had an active neutralising power against both the typhoid endotoxin and the typhoid bacillus. The results of the use of this serum in nine cases of typhoid fever were detailed. The impression which had been gained so far was that several cases were benefited and that in two at least the disease was cut short by its use. Typhoid fever was, however, such a variable disease that it was extremely difficult to estimate the value of any form of treatment unless a large number of cases was available. In no instance did the serum appear to do any harm. Unfortunately, cases of typhoid fever usually only came under observation when the disease had existed for a week or longer. If the disease had existed for some time no immediate effect could be hoped for from the use of a serum, however efficient that might be. Moreover, the existence of secondary infections, which often occurred in typhoid fever, must limit the value of any serum. As regards dosage of the serum, his impression gained from those few cases was that the serum should be given freely—namely, from 10 to 20 cubic centimetres daily—until the temperature had reached the normal, and perhaps in smaller doses for a week subsequently. Another point was that the preparation of an anti-endotoxic serum was at present in the experimental stage. They did not know for how long the horse should be immunised and he was inclined to think that it was possible *to over-immunise,* that was the serum did not increase in potency after a certain number of doses of the typhoid endotoxin; in fact, harm might result from continuing the injection of the horse. The horse seemed to be extremely susceptible to the typhoid endotoxin and a period of eight months elapsed before a dose of 30 cubic centimetres could be given. In a second horse which he was immunising the commencing dose of toxin was 0·1 cubic centimetre, and even that small *dose caused so much* disturbance that it had to be repeated five times at weekly intervals before the dose could be increased. He thought it would be of interest to test whether the typhoid endotoxin would give an ophthalmic reaction. For that purpose some typhoid endotoxin was carefully prepared, so as to eliminate as far as possible extraneous substances, and dried *in va*[illegible] marked reaction in several cases [illegible]o gave a reaction in one or two [illegible] did not give a reaction with several cases not typhoid. The interest of the observation was that the substance producing the reaction was thus shown to be an intracellular constituent of the organism.

Dr. E. W. GOODALL, of the Eastern Hospital, Homerton, read a paper detailing the results of the treatment of 26 cases of typhoid fever with the same anti-endotoxic serum. In regard to *the value of the treatment he pointed out* one fact which, before he treated a single patient with serum, led him not to be too sanguine as to its results. He referred to the advanced period of the disease at which the patients were in most instances sent to hospital. That was a fact which militated against any form of treatment, and was, he believed, one of the chief reasons why in his hands the bath treatment, for instance, had not achieved the excellent results obtained *by other physicians. Enteric fever* was a disease which varied in severity to a considerable degree within short periods of time, and the number of cases he had recorded was very small, so that it was impossible for him to speak with certainty as to the efficacy of the treatment. He could only say that it appeared to have done good in a few cases and that it was worthy of further trial. In regard to the ophthalmic reaction in ten cases of enteric fever in which the test was applied, in five the reaction was marked and in five it was slight, whereas in ten cases in which the person tested was not affected with enteric fever in one case the reaction was very marked (a case of scarlet fever), in three (all cases of scarlet fever) it was slight, and in six (four cases of scarlet fever, one case of indefinite pyrexia, and one normal person) there was no reaction.

Mr. R. M. Bruce of the Western Hospital, Fulham, sent a note on five cases of typhoid fever treated with the same anti-endotoxic serum. The number of cases treated was, of course, too small upon which to base any trustworthy conclusions, but his impression was that two at least were benefited by the injections, and that one case in which the temperature subsided on the seventeenth day would not improbably have run a more severe and prolonged course if the serum had not been used.

In answer to Dr. Moore, Dr. Goodall said that the condition of supersensitisation might last from two to five years.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

Rupture of the Uterus.

A meeting of this section was held on May 13th, Dr. Herbert R. Spencer, the President, being in the chair.

Dr. T. W. Eden read a paper on the Operative Treatment of Rupture of the Uterus, with an account of three cases treated by Abdominal Hysterectomy. Dr. Eden summarised the discussion on rupture of the uterus at the Obstetrical Society in 1900, introduced by Dr. H. R. Spencer, who related four cases treated by gauze packing, and advocated the use of this method in practically all cases. In 1901 Varnier recorded his experience of uterine rupture, condemned conservative treatment such as gauze packing, and advocated abdominal section for removal of the uterus in all serious cases. Dr. Eden then recounted the three following cases: 1. A case of rupture during version for transverse presentation in a II.-para, aged 29 years, at Charing Cross Hospital, on Jan. 22nd, 1905. Rupture was complete, the placenta having passed into the peritoneal cavity. The placenta was removed by hand, the peritoneal cavity douched through the rent, and an attempt made to pack the rent, which was very extensive, with gauze. 14 hours after delivery, as there was evidence of fresh internal bleeding, the abdomen was opened, and free bleeding found from the edges of the laceration, which the gauze packing entirely failed to control. The uterus was removed by the supravaginal method, the pelvic peritoneum was closed, and the vaginal portion of the rent was then packed from below. The patient made a good recovery. 2. A case of rupture during version with a VI.-para, aged 33 years, at Queen Charlotte's Hospital, on April 10th, 1908. She had previously been twice operated upon, the first time for retroversion, the uterus being ventrofixed; the second time for extra-uterine gestation; the pelvis was flat and "pendulous belly" was well marked. The placenta had passed into the peritoneal cavity, and the rent was complete and very extensive. Three hours after delivery the abdomen was opened, and the uterus removed by the supravaginal operation; vaginal drainage was employed and the patient made a good recovery. 3 A case of spontaneous rupture during the second stage of labour in a II -para, aged 25 years, at Charing Cross Hospital, on Jan. 17th, 1909. After a prolonged first stage, during which the membranes remained unruptured, strong labour pains set in and the head advanced well into the pelvic cavity. The patient was then violently sick and immediately became collapsed; hæmorrhage occurred from the vagina, and on examination the head was found to have receded and could no longer be felt. Diagnosis of incomplete rupture into the left broad ligament was made, and the fœtus was extracted *per vias naturales.* A complete and very extensive rupture was then discovered; the pelvis was contracted. The abdomen was opened three hours after delivery; the left ovarian artery was torn and had retracted, while still bleeding, beneath the peritoneum above the pelvic brim. The uterus was removed by the supravaginal method and vaginal drainage was employed. The patient at first rallied after the operation, but died rather suddenly seven hours later. At the post-mortem examination fresh bleeding was found to have occurred from a tear of the bladder, which had not been noticed at the operation. In considering the general question, it was pointed out that the three risks associated with this accident are shock, hæmorrhage, and sepsis. Dr. Eden believed that deep bleeding occurred with greater frequency than had been supposed, and might be met with in both complete and incomplete rupture, although the risk was greater in the former. The hæmorrhage which immediately followed the rupture usually ceased spontaneously, but recurrent bleeding was frequent, because uterine retraction could not control it, and the bleeding might in part be extra-uterine To control hæmorrhage was therefore an indication of the first importance. Cases of extensive incomplete rupture might be quite as serious as those of complete rupture and were attended by exactly the same risks. Abdominal section and removal of the uterus by the most rapid method possible was recommended because (1) it is the only certain way of controlling hæmorrhage; (2) the uterus has frequently been infected previous to the operation; (3) if the uterus is left and the patient recovers the risk of repeated rupture in a subsequent pregnancy is high. Laparotomy and suture of the rent had been shown to yield a higher mortality than hysterectomy, and, for the other reasons stated, was not to be recommended. In cases of extreme urgency it might be wiser, after opening the abdomen to control hæmorrhage, simply to pack the rent from above into the vagina and to remove the uterus a day or two later by the vaginal route.

Dr. A. L. H. Smith read a paper on Rupture of the Uterus giving details of a series of ten cases of complete rupture of the uterus, eight of which were treated in the General Lying-in Hospital, and which were the total number of examples of this accident which had occurred among 10,989 deliveries during the last 20 years. Of the ten cases nine died and one recovered. 80 per cent. of the patients were multiparæ, 20 per cent primigravidæ. The cases were divided into two classes. In the first class the rupture was due to an abnormal excitability of the uterus, resulting in a great increase in the strength and frequency of the contractions together with a premature retraction, a condition exactly similar to that produced by the administration of ergot. In the second class the rupture followed a prolonged and obstructed labour, and in some cases was possibly the result of perforation with an instrument or was due to some intra-uterine manipulation.

The President said that in considering the question of treatment it was to be borne in mind that, although rupture sometimes occurred spontaneously and in careful hands, it arose for the most part in bad and dirty midwifery practice, and consequently the tissues were often bruised and infected, and many would die however they were treated. He showed ten specimens of rupture from the Museum of University College Hospital. In two of the cases abdominal hysterectomy had been performed, with a fatal result in each case from shock. Only one of the ten cases was a suitable case for supra-vaginal hysterectomy. Total hysterectomy was indicated in those cases which required the removal of the uterus, but in his opinion these patients were usually too much shocked to stand removal of the uterus by the abdominal route

Dr. C. Hubert Roberts related four cases of rupture of the uterus which had come under his care. The first of these was treated by plugging the rent and she recovered. In the second and third cases the abdomen was opened and the rent sewn up with silkworm-gut sutures. One of these recovered and three years later was safely delivered of a full-term child at Queen Charlotte's Hospital. The fourth case died very soon after delivery before it was possible to attempt any treatment. As to treatment, Dr. Roberts thought no hard-and-fast rule could be adopted.

Dr. G. Drummond Robinson stated that he had had five cases of ruptured uterus under his care. One patient died shortly after rupture had occurred. In two cases the rupture was discovered after the delivery of the child. In both of these cases gauze-packing was employed and they both recovered. In two other cases the fœtus was still in the uterus when the rupture was discovered, and abdominal hysterectomy was performed. Both patients died. Dr. Robinson was surprised that others had not alluded to this class of rupture in which the fœtus was still in the uterus, and delivery by the vagina was contra-indicated. He thought that in cases of this kind there was no option but to perform abdominal section and at the same time to remove the uterus.

Dr. J. S. Fairbairn said he could speak only from a small experience of about six cases, in which, however, the three methods of plugging, suture of the rent, and abdominal hysterectomy had been tried. He thought that there was a place for all these forms of treatment, and that what should be aimed at was some means of recognising the cases suitable for each method. He had had three cases in which no operative treatment was done, two of which made as straightforward a recovery as any uncomplicated labour case. In one of them there was a rent through the posterior wall of the uterus which admitted three fingers, but there was no bleeding, and a gauze plug was all that was required to prevent intestinal prolapse. In another case there was an extensive laceration into the left broad ligament large enough to admit the whole hand, but not communicating with the peritoneal cavity. Nothing at all was done and she made an uninterrupted recovery. A third case in which plugging was tried died in 24 hours. In the case in which hysterectomy was done the child, who had been lying transversely, had escaped into the left broad ligament, and the placenta had been extruded into the peritoneal cavity. Both child and placenta had been delivered by the outside practitioner before the patient was admitted. She was suffering profoundly from shock and was bleeding, so the abdomen was opened. The posterior layer of the broad ligament was torn into [illegible] a bridge, and the uterine rent [illegible] course than hysterectomy was [illegible] a few hours later, as also did one mentioned by Dr. Lionel Smith, in whom partial suture of the rent and drainage were tried. These few cases exhibited such differences in symptoms that no one form of treatment would have been suitable in all.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Bier's Hyperæmia.—Post-operative Tetanus.

A MEETING of this section was held on May 7th, Mr. JOHN LENTAIGNE, the President, being in the chair.

Mr. R. ATKINSON STONEY read a paper on Bier's Method of Treatment by Hyperæmia. After mentioning the various forms of hyperæmia, he said he would confine his remarks to passive hyperæmia, produced by means of the elastic bandage and suction glasses, more especially in the treatment of septic inflammation rather than in tuberculous disease, as in the treatment of the latter type of cases his experience had been neither extensive nor promising. He described the method of applying the elastic bandage and the suction glasses, laying special stress on the necessity of not producing too great a degree of hyperæmia, as in that case serious harm might be done. He gave the following rules for the application of the bandage: (1) Place it on the limb as far from the site of the disease as convenient; (2) wind it round a broad surface of the limb to prevent local pressure and pain; (3) do not bandage with sufficient force to weaken the pulse distally; (4) no pain should be caused in the diseased part, rather any existing pain should disappear; (5) the distal part should be bright or dark red, not blue, and should be warmer than the corresponding part on the opposite limb, not colder; and (6) the bandage, for all except tuberculous cases, should be left in position for two periods of 8 to 11 hours or one period of 16 to 22 hours out of the 24. In the case of the suction glasses ordinary aseptic precautions should be observed. A glass of sufficient size should be chosen to leave a margin of one inch or more around the inflamed part or opening, to prevent strangulation or compression of the lips of the opening. Pain should not be produced. And, especially where the cup was placed over a superficial bone or firm membrane, excessive pressure should not be used for fear of sloughing of the parts. Some cases were briefly described illustrating the use of both these forms of application of passive hyperæmia in various conditions.—The PRESIDENT said he had recently been converted to the treatment for boils, but he had seen a great number of cases of tuberculous disease which had deteriorated by the treatment, and in some cases he could not satisfy himself that the dissemination of the tuberculosis had not been in some way due to it.—Mr. K. E. L. G. GUNN said he had tried the treatment in cases of knee and wrist trouble, but found it impossible to produce any degree of congestion without pain.—Mr. W. I. DE C. WHEELER confessed the same experience as Mr. Gunn, but in cases such as gonorrhœal rheumatism he did find some easing of pain and apparently some improvement.—Mr. STONEY, in reply, said the worst results had been got by Bier in the knee-joint, for some reason which he could not explain. He did not suggest the treatment in any case where better results, or quicker equal results, could be obtained by operative means. It was in tuberculous cases that the greatest difficulty was found in producing the correct degree of hyperæmia. The question of tension was difficult to deal with. It was, however, easy to understand that pain, which might be due to irritation of the nerve terminals by toxins produced by organisms, might be relieved by the congestion causing a flow of blood and lymph and producing a dilution of the toxins.

Mr. GUNN read a paper on Post-operative Tetanus.—The PRESIDENT said the paper was one of the most valuable which had been read before the Academy. He could imagine no more appalling catastrophe to happen a surgeon than to have a case, or series of cases, of post-operative tetanus. He could not help keeping to the belief that the catgut used must have been responsible. It was curious that in every case in which the catastrophe had occurred catgut had been used. It would be important to know what methods of sterilisation had been employed. He had himself been using the iodine catgut for some time, but if he was threatened by the terrible phantom of possible tetanus he would be inclined to give up catgut altogether.—Dr. KATHARINE MAGUIRE said she had been in attendance on one of the cases mentioned by Mr. Gunn. It was not a case of hysterectomy alone, but was combined with ovarian tumour, and quantities of thick catgut had been used.—Mr. A. J. BLAYNEY said it seemed difficult to get over the fact that in every single case catgut had been used. They knew the source of the catgut and the probability of its being infected, which made the conclusion of its responsibility all the more probable. The extreme virulence of the cases seemed to be at variance with the results of the bacteriological examination. The conditions inside the body were not such as would be expected to favour the growth of the bacillus; in two of the cases there was no suppuration and therefore no septic organism to prepare the way for the bacillus, and the tissues were well supplied with oxygen, which was also unfavourable to the bacillus.

SECTION OF MEDICINE.

Exhibition of Cases.—Grocco's Triangle.

A MEETING of this section was held on May 14th, Dr. W. G. SMITH, the President, being in the chair.

Dr. O'CARROLL and Dr. F. C. PURSER exhibited a case which had been diagnosed as Locomotor Ataxy. The patient was a young man, 23 years of age, married at 19, the father of two healthy children. The wife had had no miscarriages. There was a distinct history of congenital lues. About a year ago he got suddenly weak in his left leg, with a pain in his knee. Since then he had had a progressive difficulty in walking. Some two years previously he had "seen double" for a short time. His present condition was that without paralysis of any muscles he had considerable difficulty in walking and was very ataxic. The knee-jerks were absent. The pupils contracted neither to accommodation nor light. He appeared to have no loss of sensation in the limbs, but was rather slow in recognising touches on the left leg, especially from the knee down.

Dr. H. C. DRURY [illegible] Ataxia —sisters, aged 11 an [illegible] been noticed about three [illegible] anger was the much more advanced case. She stood fairly well with the feet apart, but could not balance at all with her eyes closed. The elder girl had sometimes a slight shaking of the hand, which was only noticeable when watching closely. There was no sensory disturbance or disturbance of the sphincters. The eye symptoms were variable. In the younger girl there was slight nystagmus, but some days it was absent altogether. In both cases there was a total loss of knee-jerks. The limbs were well nourished. The younger girl showed well-marked lateral curvature, and both feet were getting flat. She had a systolic murmur heard near the apex; and at the base of the heart she had a loud systolic murmur when lying down, which disappeared when she sat up. The day following the observation of the latter murmur it was exactly the reverse—that is, it was absent when lying down, and present when erect; it varied from day to day. Her sister had the same. When they went to hospital they were very thin, but they had grown fatter and better in colour after a couple of months on arsenic. Dr. Drury also exhibited a case of Idiopathic Muscular Atrophy in a man, aged 24 years.

Dr. T. G. Moorhead read a paper on Grocco's Triangle, giving his observations on the subject for some years past.—Dr. T. P. C. Kirkpatrick said he had looked for the sign during the past two years and had endeavoured to demonstrate it. He could sometimes demonstrate it to his own satisfaction, but he had often failed to do so to others looking on. It was in cases of small effusion that the sign was of particular value and it was in such cases that it was very difficult to elicit it.—The President said that, short of post-mortem evidence, some mystification hung over the subject. It took ten ounces of fluid to produce recognisable physical signs, and in cases of large effusion the sign was hardly necessary.—Dr. Moorhead, in reply, said he was an advocate of early removal of fluid, and endeavoured to demonstrate it. In three of the five cases in which he did not get the sign he also demonstrated fluid, but he had not been able to demonstrate the relationship between the size of the triangle and the effusion.

Bradford Medico-Chirurgical Society.—A meeting of this society was held on May 18th, Dr. W. Ward-Smith (Vice-President) being in the chair. The following specimens were exhibited:—Dr. C. F. M. Althorp: (1) Intestinal Obstruction due to Gall-stones; and (2) Tumour of Testicle.—Dr. A. Bronner: (1) Cholesteatoma of External Auditory Meatus; and (2) Papillomata removed from the Larynx.—Dr. Lockerbie: (1) Placental Polypus; and (2) Uterine Fibroid.—Dr. T. Jason Wood: (1) Ovarian Dermoid; (2) Hydrocele of Cord; (3) two specimens of Prostatic Enlargement; and (4) some varieties of Uterine Fibroid.—Dr. F. W. Eurich: (1) Specimen from case of Nitric Acid Poisoning; and (2) Thymus from a child, aged two years, weighing two ounces.—Dr. Charles Stiebel: Intrapancreatic Aneurysm.—Dr. W. Mitchell read a paper entitled "Some Tuberculous Skin Diseases." He said that the first variety, tuberculosis cutis vera, was rare and was simply an infection from within at the orifice of a mucous outlet—e.g., round the mouth in pulmonary tuberculosis. Treatment was not in this case of much use owing to the constant re-infection. The second variety, tuberculosis verrucosa, was due to infection from without and was somewhat rare. The treatment consisted in applying preparations of salicylic acid or pyrogallol, curetting, and treating with Finsen light or with x rays. The third variety, scrofuloderma, was not, strictly speaking, a primary disease of the skin, but arose from a caseating gland or bone lesion in the subcutaneous tissues. The treatment consisted in removing the original focus of the disease and applying antiseptic dressings. The fourth variety, lupus vulgaris, was a chronic cellular overgrowth due to the invasion of the skin by the tubercle bacillus. After enumerating various methods of constitutional treatment which had been tried in this disease, he said that many eminent authorities strongly advocated the use of the new tuberculin and that with regard to local measures the x ray treatment was the most successful of all.—A discussion followed.—Dr. Eurich suggested that in those cases which did not yield readily to x ray treatment tuberculin should be tried as well. Very often the combination succeeded where either treatment separately was ineffectual.—Mr. F. W. Goyder agreed with the last speaker. He was also greatly in favour of excision where possible and thought that scraping in many cases was distinctly useful.—Dr. Ward-Smith compared the treatment now with that of five years ago when he was in charge of the x ray department.—Dr. Lockerbie asked if the x ray treatment ever caused epithelioma.—Dr. Bronner said that he had been very successful with scraping combined with the application of pure formalin.—Dr. Mitchell then replied.—Dr. H. J. Campbell read a paper on the Therapeutic Uses of Alcohol. After describing the physiological action of alcohol on the various tissues and systems of the body, Dr. Campbell summed up as follows: Alcohol should be avoided in all cases of deficient elimination—e.g., kidney disease; in all cases where a pernicious habit is likely to be acquired, as in neurasthenics and women at the climacteric; in all cases of chronic nervous depression and in all conditions where prolonged mental or muscular strain has to be undertaken; and in all cases where there is a condition which is likely to recur. The drug is useful under suitable conditions of administration as a cardiac and respiratory stimulant and promoter of appetite.

United Services Medical Society.—A meeting of this society was held on May 19th, Lieutenant-Colonel W. G. Macpherson, R.A.M.C., being in the chair.—Major H. W. Grattan, R.A.M.C., and Captain A. L. A. Webb, R.A.M.C., communicated a paper and gave a demonstration of the method of the preparation of the antityphoid vaccine for the army. They said that the vaccine was prepared at the Royal Army Medical College, and that during the last 12 months they had prepared and issued 40,800 double doses for the use of the army both at home and abroad. They stated that the vaccine was prepared from the broth culture of the typhoid bacillus, and demonstrated the various steps of the technique. A few of the points upon which they laid special stress were: that the culture should not be overheated (a temperature over 53° C. having been found to have a deleterious effect on the immunising properties of the vaccine), that the antiseptic (0·25 per cent. lysol) should not be added until the vaccine had cooled down, and that the vaccine should not be used later than three months from the date of manufacture. These conclusions had been arrived at as the result of experimental work on the protective substances found in the blood of men and animals inoculated with vaccines prepared at different temperatures and of different ages. They quoted the most recent statistics available, which had been compiled by Brevet-Lieutenant-Colonel W. B. Leishman, R.A.M.C., and published in the February number of the *Journal of the Royal Army Medical Corps*. The total strength of the 16 units under observation was 12,083; of these 5473 were inoculated, amongst whom 21 cases of enteric fever occurred with two deaths. The remaining 6610 non-inoculated men served as a control, amongst whom occurred no less than 187 cases of enteric fever with 26 deaths.

Medico-Legal Society.—A meeting of this society was held on May 25th, Dr. J. Scott being in the chair.—Dr. Charles A. Mercier read a brief note on the recent case of Rex *v.* Governor of Stafford Prison (*ex-parte* Emery), in which a deaf mute accused of a felony was held by the Divisional Court unable to plead and was ordered to be detained as non-sane.—Mr. S. R. C. Bosanquet, Dr. F. J. Smith, and Dr. S. B. Atkinson joined in the discussion.—Dr. T. Claye Shaw followed with a paper entitled "On a Prominent Motive in Murder," taking the "lust for blood" as his theme.—There also spoke Earl Russell, Mr. H. Sweeney, Dr. Mercier, and Dr. W. A. Brend.—The following proposition was moved by Dr. Mercier and carried:—

> That in the opinion of this society it is urgently necessary that legislation to amend the Inebriates Act should be introduced without delay.

The honorary secretaries were deputed to bring the society's resolution to the notice of the proper authorities.—The annual meeting and dinner of the society will take place at the Holborn Restaurant on July 13th, when the Hon. Mr. Justice Walton, the President, will take the chair.

Medical Motorists and the Budget.—On May 25th Mr. C. B. Lockwood, of St. Bartholomew's Hospital, occupied the chair at a special meeting of the Motor Union Committee of Medical Motorists held at the offices of the union to consider the Budget proposals of the Chancellor of the Exchequer in so far as they affect members of the medical profession using motor cars. There was a representative attendance of medical men, members having travelled from the North and West of England in order to be present at the meeting. The committee resolved that the motor-car has now become an absolute necessity to a medical practitioner, who is, therefore, entitled to make a special claim for abatement. It was resolved to approach the Chancellor of the Exchequer with a view to securing a rebate of 1½*d.* per gallon on petrol used by medical men. A letter was read from Mr. W. Joynson Hicks, M.P. (chairman of the Motor Union), stating that the Chancellor had agreed to receive a deputation on the matter.

Reviews and Notices of Books.

The Collected Papers of Joseph, Baron Lister, Member of the Order of Merit, Fellow and sometime President of the Royal Society, Knight Grand Cross of the Danish Order of the Danebrog, Knight of the Prussian Order pour le Mérite, Associé Étranger de l'Institut de France, &c. In two volumes. Vol. I., pp. 410; Vol. II., pp. 552. Oxford: At the Clarendon Press. 1908. Price £2 2*s.* each volume.

IN many foreign universities, especially in Germany, it is the custom to honour the jubilee of a professor or his retirement from his post by the publication of a "Festschrift"; this usually takes the form of a volume containing contributions relating to the branch of knowledge for which he has been famous, and written by his friends and former pupils who take pleasure in thus showing their respect and their gratitude for the teaching they received from him years before. In this country the practice is almost unknown, and we cannot but regret this. We do, indeed, on occasion celebrate important events in the life of an honoured teacher, but it is seldom that the celebration goes farther than a dinner. There are, however, exceptions, and the volumes before us form a very appropriate memorial of Lord Lister's eightieth birthday. On April 5th, 1907, he reached the age of 80 years and he received many congratulations, not only from his own countrymen but from representatives of medicine and surgery in all parts of the civilised world. It was then felt that some permanent memorial should be instituted of an occasion so happy and of a life so rich in benefits to all the human race. It was therefore determined by those most fitted to judge that no more appropriate memorial could be chosen than an edition of his scientific papers, collected together from the many magazines and journals in which they had appeared, for in these papers are recorded the several steps by which was brought about the great revolution which will always be associated with his name, and in them those who come after will be able to find the great principles on which that revolution was founded. Lord Lister approved of the idea, and the two volumes now issued contain all the paper and addresses which he himself considers to be of permanent interest and importance; those only have been omitted which were addresses on some official occasions and dealt with matters of ephemeral or merely local interest. The committee responsible for preparing these volumes for the press consisted of Sir Hector Cameron, Sir W. Watson Cheyne, Mr Rickman J. Godlee, Dr. C. J. Martin, and Dr. Dawson Williams, and the result does infinite credit to them.

The contents of these volumes have been classified under four heads: those in the first part deal with physiology, and those in the second part with pathology and bacteriology; in the third are papers on the antiseptic system and on general surgery, and in the fourth part are included general addresses and lectures. With regard to physiology, it is of interest to note the particulars with which the papers deal. In reading these articles and in appraising their value it must not be forgotten that the great discoveries of one generation become the commonplaces of the next, and in this case nearly two generations have passed since the first paper was published in 1853. The first three articles deal with the structure of involuntary muscular fibres. Five years before Kölliker had for the first time explained the cellular structure of all plain muscular fibres, and the researches contained in these papers were intended to confirm and extend the opinions which had been put forward by Kölliker, and this they succeeded in doing very satisfactorily. Although we have attained to a more thorough knowledge of involuntary muscle fibres, yet the advance indicated by our present knowledge is hardly so great as might have been expected. Some papers follow on the nerve-supply of arteries and the cutaneous pigmentary system of the frog, and then come several important articles dealing with the subject of the coagulation of the blood. The earliest of these recorded a large number of experiments, performed to test the various theories of coagulation which were then current. The most recent of these was the ammonia theory of that most ingenious and versatile of observers, Sir Benjamin Ward Richardson, who explained coagulation as being due to the escape of ammonia from the blood. Lister was at first inclined to accept this theory, but as he performed more and more experiments he was compelled to abandon it. He tested in turn the other current theories but found them all wanting; yet he was not insistent on propounding any rival theory: he merely stated the facts which appeared to be proved by the experiments he performed. The reader of these papers cannot fail to be struck by the judicial position maintained by the writer; even with regard to his own observations he never degenerates into a special pleader. The articles on coagulation were spread over a long period, the earliest appearing in 1858 and the latest in 1891.

Next in order we come to the section dealing with pathology and bacteriology, which is of more immediate importance from a medical point of view. This includes nine papers: the most important being, first, one on the early stages of inflammation, published in 1857, containing much that was new; and secondly, several dealing with fermentation and the relations of micro-organisms to disease, the earliest of which dates from 1873, being subsequent to the enunciation of the practice of antisepis. This paper is concerned with the influence of the medium on the growth of an organism, as exemplified especially by torulæ. Two others deal with the nature of fermentation as shown in the changes which occur in milk; another treats of the relations of micro-organisms to disease; and still another of their relations to inflammation, the opinion being expressed that many conditions influence the occurrence of inflammation, while the value of counter-irritation as a therapeutic measure is extolled. In these papers, which we need not discuss in detail, we have evidence of the care with which Lister deals with controversial matters; though he was himself the introducer of the idea that the presence of organisms caused inflammation and suppuration in wounds, yet he brings forward evidence, not conclusive in all cases we must now deem it, which tends to show that some inflammations may occur without the aid of micro-organisms.

The third part contains, as we have already mentioned, papers on the Antiseptic System and on General Surgery. The first articles dealing with the antiseptic system appeared in THE LANCET in 1867; they were entitled "On a New Method of Treating Compound Fracture, Abscess, &c.," and commence with the following sentence: "The frequency of disastrous consequences in compound fracture, contrasted with the complete immunity from danger to life or limb in simple fracture, is one of the most striking as well as melancholy facts in surgical practice." This is the keynote of the paper—what is it that prevents a compound fracture from healing as readily as one that has no communication with the outer air? Lister says at once that the decomposition of animal matter in the wound is produced by the entrance of germs with the air, and he also points out that it is probable that the pernicious effects of decomposing animal matter upon the tissues had been underrated. He cites in proof of this doctrine the harmlessness of a pneumothorax resulting from puncture of the lung by a fractured rib, which proves that atmospheric air in itself is not harmful, and he contrasts the ready absorption of the air in a pneumothorax so produced with the harmful results of a pneumothorax caused by an external wound. It occurred to him that if it were possible to dress the wound in a compound fracture with some substance capable of killing these septic germs it should heal like a simple fracture. A year earlier he had seen that carbolic acid prevented the odour from decomposing sewage, and he determined to employ it for treating compound fractures. The first case, in May, 1865, was a failure, but in August a success was obtained. Other successes followed, and the technique varied, with the results which he now began to obtain. Sometimes merely lint dipped in liquid carbolic acid was laid on the wound, and in others a carbolic putty was employed; pieces of sheet tin were also tried to keep the carbolic acid in the dressing. The events were surprisingly good, though the means employed seem now to be extremely crude. In all 12 cases are mentioned, and of these two died. The first fatal case *should, perhaps, hardly be counted in the series, for the* method was only being devised; and the other patient died from hæmorrhage from the femoral artery caused by pressure of a fragment of the broken bone. This second case had survived the original accident four months, so that even in it the method could not be described as absolutely a failure. The same paper contains an account of a method of opening chronic abscesses, such as those of the psoas, by which septic infection was prevented, where Lister showed that if the skin is covered by a rag soaked in carbolic oil and the incision is made under this, one edge being lifted up for the purpose, the pus can escape but germs do not enter. The re-dressings were performed with similar precautions, and the happy issue of a number of cases demonstrated the success of the method and the truth of the theory.

At the Dublin meeting of the British Medical Association in 1867 Lister read a paper on the Antiseptic Principle in the Practice of Surgery, and in this paper we find it laid down as conclusively proved that "all the local inflammatory mischief and general febrile disturbance which follow severe injuries are due to the irritating and poisonous influence of decomposing blood or sloughs," with the striking commentary that "these evils are entirely avoided by the antiseptic treatment." We find the carbolic putty again recommended, but it is advised to apply it in a layer a quarter of an inch thick between two pieces of thin calico. Here also we find the first published reference to the antiseptic method being employed for amputation and for strangulated hernia, and the statement that ligatures may safely be cut short; and, lastly, Lister points out the effect on his wards in the Glasgow Royal Infirmary of antiseptic treatment. He tells us that while the ventilation of these wards was very bad, whenever nearly all the beds contained open sores, hospital gangrene and pyæmia were almost sure to show themselves; but when the antiseptic treatment had been brought into full operation the general condition of the wards greatly improved, so that during the nine months immediately preceding the reading of the paper not a single case of pyæmia, hospital gangrene, or erysipelas had occurred in them.

The succeeding papers are mainly concerned with records of individual cases in which the antiseptic method had been employed and with accounts of modifications of the method suggested by a widening experience. Various antiseptic plasters are tried; notably a combination of shellac with carbolic acid proved useful, and various operations are described in which the method had been performed. In one case a penetrating wound of the thorax and abdomen with prolapse of omentum was treated successfully and an empyema did not develop, as in those days might have been confidently expected; and in another case an acute infective periostitis of the tibia healed well. A case of old fracture at the ankle with a fixed displacement of the foot was treated by an open operation and the foot replaced in position without any septic complications occurring; in fact, it is obvious that Lister was discovering that the field of the activity of the surgeon was being greatly widened. Here also we find an account of a successful ligature of the external iliac artery in its continuity, the ligature being cut short. Two papers on the value of catgut for ligatures and sutures follow and detailed accounts are given of the method of preparation and the desiderata in catgut to be used for surgical purposes. The later of these papers appeared in THE LANCET only last year.

Other articles included have appeared in the medical press from time to time dealing with important cases treated by the antiseptic method—for instance, the case of a man, 30 years old, who was struck by a railway engine and sustained a compound fracture of an ankle, a compound fracture of an elbow, and extensive scalp wounds baring the bone; recovery follows the treatment adopted, and *Lister shows by the method which he describes that though* he may vary the details the principles of therapy remain the same, and that thoroughness of the practice remains the one essential factor. In reference to this case he points out that the antiseptic is not applied to the surface of the wound after the original application; the tissues having been freed from the germs which had infected the wound are allowed to recover unirritated by antiseptic applications. He describes various forms of protection, the special function of which is to exclude the antiseptic of the dressing from the wound. In 1870 there appeared in the *British Medical Journal* Lister's suggestions for the application of the antiseptic method to the wounded in the Franco-Prussian war which was then raging, and the suggestions represent the treatment reduced to what he thought to be its minimum—the very least, i.e., that could be done in the circumstances. In a case reported in 1871, in which Lister operated for the improvement of a vicious union of a fractured forearm, we first hear of the use of the carbolic spray during the operation, and for the dressing oakum was employed successfully in place of carbolic putty or lac-plaster. The oakum soon led to the use of gauze impregnated with carbolic acid, resin, and paraffin, while a layer of guttapercha tissue prevented the discharge from soaking directly through the dressing. In the Address on Surgery at the Plymouth meeting of the British Medical Association held in 1871 Lister gave a full account of the method he then pursued; in this address we have the first description of cotton-wool employed as a dressing, and the reason for its use is stated to be its power of filtration of minute particles from the air as described by Tyndall. In this paper also we first find the expression antiseptic gauze. In 1875 articles on recent improvements in the details of antiseptic surgery appeared in THE LANCET, and a description was given of the methods of preparing gauze and sponges, while an account was included of the use of boric acid, and some details of drainage were also described. When the British Medical Association met at Edinburgh in 1875, Lister, as president of the Surgical Section, delivered an address on the effect of antiseptic surgery in improving the condition of hospitals, and he gave some demonstrations and performed some operations before members of the Association. In 1881, when the International Medical Congress was held in London, Lister gave an address on the treatment of wounds, in which he re-stated the case in favour of the antiseptic method. The search for even more perfect means led in 1884 to the publication of a paper on the use of corrosive sublimate as a surgical dressing, in which he points out the desirability of having a non-volatile antiseptic if possible. In order to diminish the irritation he combines the corrosive sublimate with the albumin contained in horse serum, and afterwards uses sal alembroth, while later still, in 1889, the double cyanide of zinc and mercury is brought forward as being more useful than corrosive sublimate. A paper read at the International Medical Congress at Berlin in 1890 marks further advances: the spray had been abandoned and less and less antiseptic was being applied to the surface of wounds, so that the amount of discharge was less, and less drainage was needed. A contribution to the Virchow-Festschrift in 1891 reaffirmed the principles of antiseptic surgery, and a short letter to Sir Hector Cameron on some points in the history of antiseptic surgery, written in 1906 and published in THE LANCET in 1908, concludes the first division of this section of the work. The most remarkable of the six papers on general surgery which comprise the second division of the section are one on excision of the wrist for caries, in which Lister describes his well-known operation, and one on the treatment of fracture of the patella, the reprint of an address delivered before the Medical Society of London in 1883. This paper is supplemented by one on fractures of the patella of long standing, which was published only last year in our columns. The article on amputation in Holmes's "System of Surgery" was also from Lister's pen, and is here reproduced.

All the addresses which form the concluding part of the volume are of interest, especially that on the interdependence of science and the healing art, delivered at Liverpool in 1896, in which Lister showed how the whole of the progress of medicine and surgery is dependent on the scientific study of the causes and phenomena of disease. The third Huxley lecture, delivered at Charing Cross Hospital in 1900, contains a *résumé* of Lister's scientific work, and the concluding article, an obituary notice of Lister's father, is of interest, for he did much to improve achromatic microscopes, and his influence on the direction of his son's work was doubtless great. The mass contained in these volumes has compelled us to notice some of the papers rather cursorily, but each is deserving of perusal as the work of a pioneer, and we think that no better memorial of their distinguished author could have been devised. It affords us the greatest pleasure to bear witness to the clearness and the thoroughness with which these papers have been written: their permanent value is assured as a record from year to year of the most important advance in surgery that the world has ever known.

Practical Bacteriology, Blood Work, and Animal Parasitology, including Bacteriological Keys, Zoological Tables, and Explanatory Clinical Notes. By E. R. STITT, A.B., Ph.G., M.D., Surgeon, U.S. Navy; Graduate, London School of Tropical Medicine; Instructor in Bacteriology and Tropical Medicine, U.S. Naval Medical School; Lecturer on Tropical Medicine, Jefferson Medical College. With 86 illustrations. London: H. K. Lewis. 1909. Pp. 294. Price 6*s.* 6*d.* net.

THIS is a small book, of less than 300 pages, in which the author essays to treat of bacteriology, hæmatology, and animal parasitology. It is natural for the reviewer to look askance at such an attempt, but it must be confessed that, within certain self-imposed limits, Dr. Stitt has been singularly successful and has produced a work of real value. It is not a book from which to learn systematic bacteriology, nor is it perhaps suitable for the elementary practical class, but for the man who has had some training in laboratory work, and is able to make use of the short descriptions and many practical hints contained in the work, it will prove extremely useful. The book is described as "practical," and the right to use the adjective is most fully earned. It is founded on the experience of the author gained in examining and teaching candidates for the American Naval Medical Service. This experience, which rests upon a knowledge of the work of medical graduates already to some extent trained, leads the author, we think, to under-estimate the difficulties of the less advanced student, and to regard the book as suitable for a somewhat larger circle of workers than is justifiable.

Perhaps the most characteristic features of the volume are its definiteness of statement and the use made of "keys" or classifications, both for the scientific arrangement of the organisms treated and for the practical purpose of their ready separation and identification. This classification is especially valuable in the section on animal parasitology, as the student usually finds much difficulty in this direction. The practical object of the book is also well served by the illustrations, in which ova, parasites, &c., are arranged in groups for the purpose of comparison and discrimination. The opening section deals with bacteriology and treats of the methods of culture, staining, and identification of micro-organisms. This is followed by a short description of the principal pathogenic organisms, especial stress being laid upon the features which serve for their differentiation. Immunity is discussed shortly in its theoretical aspects, but only as the basis for the practical application of methods for the production of the various agglutinating and hæmolysing sera which are of use in diagnosis. In this section it is to be noticed that the theoretical "side chains" of Ehrlich's hypothesis are spoken of as "protoplasmic particles"; it is a fate which was sure to overtake this conception sooner or later. The section on hæmatology is, so far as its limits allow, accurate and satisfactory. Animal parasitology occupies about half the book, and the information given will prove most useful to medical men working at this subject.

The volume is well printed and well illustrated. It will be especially valuable to medical officers of the naval or colonial service, as well as to the majority of practitioners following their profession in tropical climates.

The Fluids of the Body. (Mercers' Company Lectures.) By ERNEST H. STARLING, M.D. Lond., F.R.C.P. Lond., F.R.S. London: Archibald Constable and Co., Limited. 1909. Pp. 186. Price 6*s.* net.

IN 1859 Claude Bernard published his famous "Leçons sur les Liquides de l'Organisme," which dealt with all the fluids of the body. Professor Starling's lectures—eight in all—are more restricted in their scope, for they deal with the physical properties of protoplasm, osmotic relations of cells, intake of fluid, exchange of fluids and production of lymph, absorption of the interstitial fluids, output of fluid, fluid balance of the body, and the causation of dropsy. The last is an Arris and Gale lecture of 1896, with certain alterations necessitated by recent work on the subject. If protoplasm must be regarded as a fluid, and as consisting of a solution or suspension in water of compounds of very varying complexity, then the energies displayed by living cells must be derived from the energies of substances in solution. They are derivable from, and measurable in terms of, osmotic energy, and of surface energy when occurring at the dividing surface between the living cell and its environment. The available energy of a cell may be regarded as made up of two factors—namely, (1) the total osmotic pressure of all the dissolved substances present in the cell; and (2) the chemical energy of those substances. This is the theme of the first lecture. An interesting account is given of colloids and their importance—their instability, the surface phenomena of colloidal solutions—as the changes in cells take place in a colloidal medium.

The importance of the "Plasmahaut," or superficial layer of protoplasm, in maintaining the "privacy of cell life," and its "qualitative permeability" form an integral part of the lecture on Osmotic Relationships of Cells. The medium surrounding the cells must have a definite osmotic pressure, and this pressure must be supplied by specific salts. The cœlomic fluid—the internal medium of higher animals, representing blood, lymph, and tissue fluid—was probably at its first appearance in the history of its evolution simply an enclosed portion of the surrounding medium or sea-water; and indeed "the three elements sodium, potassium, and calcium are in proportion very much like those that now obtain in sea water." By its means the cells obtain an average constancy of environment. They can thus devote their entire energies to the discharge of their particular functions. The intake of water, regulated through the intermediation of the central nervous system, occurs chiefly in the small intestine; and the cells of the intestinal villi are probably lipoid in character, and therefore physically permeable only by such substances as are soluble in such a membrane—e.g., water, urea, alcohol. The transference of water from the lumen of the gut into the blood stream is effected by forces having their origin in the epithelial cells themselves. The fourth lecture deals with the importance of the "tissue fluid"—which is the real internal medium of the body—and with lymph production. Absorption from serous cavities and from connective-tissue spaces is next dealt with. As to the "output of fluid" (Lecture VI.), the function of the kidney is to keep the composition of the circulating fluid constant, and this organ possesses "in the highest degree the phenomenon of 'sensibility,' the power of reacting to various stimuli in a direction which is appropriate for the survival of the organism." The author next discusses the dual nature of the kidney's activity, glomerular and tubular; and reviewing all the experimental facts, he concludes that they do not negative the view that the glomerular epithelium plays the part of a passive filter in the formation of urine (p. 120). As to the renal tubules they both secrete and absorb, and thus modify the glomerular transudate, not only by the absorption of water but also by the absorption of dissolved constituents. "An absorptive mechanism, sensitive to and reflecting the nutritive condition of the whole body, especially as concerns water and salts, is needed in the tubules" (p. 132). The "fluid balance of the body" is studied under the heads of plethora brought about by increasing the total volume of blood, or by the introduction of normal saline solution—hydræmic plethora; and of anæmia—i.e., a diminution of the total volume of the blood. The guiding principle in regard to the maintenance of the arterial blood pressure is the need of the master tissue of the body—the brain—for a constant supply of blood and oxygen; indeed, the whole vascular system is subordinate in its activity to the needs of the brain (p. 147). The last lecture is a useful corollary to the foregoing, and though we are told that "the causation of dropsy in Bright's disease is at present enshrouded in ignorance," the eighth lecture is one of the most interesting and practical in the whole series.

No one is better qualified than Professor Starling to discourse on the fluids of the body—a subject which his own researches have done so much to advance; and the interest of the reader is maintained, not only by the masterly grouping and orderly arrangement of facts, but by the convincing cogency of the arguments.

LIBRARY TABLE.

Friedberger and Fröhner's Veterinary Pathology. Authorised Translation by Captain M. H. HAYES, F.R.C.V.S., with Bacteriological Notes by Professor R. T. HEWLETT, M.D. Lond., D.P.H. Sixth edition. London: Hurst and Blackett. 1908. Pp. 1433. Two volumes. Price 21*s.* net.—Every up-to-date veterinarian acknowledges this work as the standard text-book on the diseases of animals, and the late Captain Hayes did the profession a very valuable service when he made this translation from the German. When it is mentioned that the book has been translated into French and is accepted as a standard text-book in the French veterinary colleges, it will easily be understood that the opinions of Friedberger and Fröhner are highly valued by veterinary practitioners. There is also an American translation which has had a very extensive sale. It is not, however, only to veterinarians that the book appeals, but to the medical officer of health as well. Apart from the wide view which it gives of the comparative aspect of disease in the various domesticated and wild animals and birds, it touches briefly upon analogous diseases in man, and the opinions given are broad-minded and rational. Especially is it useful to the medical man who is in constant or frequent contact with a veterinary *confrère*, as by a reference to one or other of the volumes he can in a lucid manner and within a very few minutes obtain most valuable information in regard to the contagious diseases of animals and birds. Such diseases as anthrax, tuberculosis, rabies, glanders, trichinosis, actinomycosis, and many others which are communicable to man are fully dealt with, whilst in other diseases, as, for example, diphtheria, scarlet fever, and measles, the pitfalls into which an inexperienced medical man may fall can be readily avoided by a perusal of the paragraphs on these ailments. To single out the description of any one particular disease for special mention and allusion here is quite unnecessary; all are equally well and fairly described, and in a manner which does great credit to the authors. It is a book which every medical man who is at all interested in the diseases of animals should possess and peruse, for it contains a mine of most trustworthy and up-to-date information.

The General Characters of the Proteins. By S. B. SCHRYVER, Ph.D., D.Sc. London: Longmans, Green, and Co. 1909. Pp. 86. Price 2*s.* 6*d.* net.—This "essay" is one of a series of excellent monographs written by an author who has been working steadily at the difficult subject of the properties of proteins, with the object of determining how far they are of value for devising methods of isolation and identification of individual members of the class. The author, however, admits that these methods are still very unsatisfactory—nay, they are even extremely defective in their character. Even the biological methods which are available for the physiologist are beyond the scope of the worker whose only resource is a laboratory for pure chemistry. The physical properties of proteins are first dealt with, such as their solubility, their behaviour on "salting-out," their susceptibility as regards crystallisation and coagulation, their optical relations, molecular weight, electrical conductivity, and fractional filtration. Then follow their chemical characters—e.g., colour and other reactions, their N. S. and P. constituents, oxidative products, and the action of reagents on them. The reader, to profit fully, must read along with this work the two sister volumes on "The Chemical Constitution of the Proteins," by R. H. Aders Plimmer. This monograph will prove most useful as an excellent *résumé* of the subject with which it deals.

Text-book of Experimental Psychology. By CHARLES S. MYERS. London: Edward Arnold. 1909. Pp. 432 Price 8*s.* 6*d.*—In this work the author does not offer a systematic psychology, but a description of the methods and principles of psychological experiment and an exposition of the most important results that have emerged in this field of research. It is at the outset made clear that experimental psychology is no new subject; it is, at least, as old as Aristotle. Far from being independent of general psychology, it has arisen from it as a refinement, while familiarity with general psychology is essential to success in experimental psychology. It is only the possibility of giving a physical expression to mental states which confers on both general and experimental psychology the rank of a science, and this physical expression is obtained by the observation of the subject's outward behaviour, and by the description of the subject's inner experience. A large portion of the book is occupied with a study of the sensations, and the rest contains chapters on statistical methods, reaction times, memory, attention, and kindred subjects. The book concludes with lucid descriptions of the numerous experiments which may be conducted in psychological laboratories. We can confidently recommend the work as a valuable guide for the student of a complex science.

Röntgen Ray Wrinkles. By LESLIE MILLER. Price 1*s.* net.—This little pamphlet may be correctly described as an epitome of the science of x ray photography in so far as the management of the apparatus is concerned. Mr. Miller, who is a practical electrician with a wide experience of x ray procedures, is to be congratulated upon the amount of valuable and accurate information, stated in clear language, that he has succeeded in condensing into such a small space. To the novice it should prove of invaluable assistance in dealing with the numerous pitfalls that impede his progress, and so complete is it that the more advanced x ray worker is almost certain to find new ideas and possibly also help out of an unusual difficulty. We note a point stated by the author which has never been sufficiently insisted upon—namely, that no matter how large the coil may be the discharging pillars should be so placed that the points can never be separated more than eight inches. Working a coil to see *how long a spark it will give is a serious strain* on its insulation and one that should be avoided. The section devoted to x ray tubes is a very good one, and an observance of the directions there given should meet with good results as well as a long life for the tube itself. Here the beginner learns to understand some of the vagaries of the fascinating, but at times very exasperating, sources of the x rays, such knowledge being, of course, the foundation of the successful practice of radiography. The pamphlet may be obtained from the author, at 66, Hatton-garden, London, E.C.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held at Caxton House, Westminster, on May 27th, with Dr. F. H. Champneys in the chair. The chairman, referr [illegible] by the Director of Public [illegible] certificates under Section 11 [illegible] medical men amongst others sometimes signed certificates and similar documents without as full an inquiry into the circumstances of the case as was desirable. The chairman said that the Board was anxious to have the abuse stopped, and he hoped that the proceedings would have a salutary effect and that certificates would be more carefully looked into before they were signed. A letter was read from the clerk of the West Sussex county council, suggesting that the local supervising authority should be temporarily enabled to permit uncertified women approved by them to practise as midwives after March 31st, 1910, in certain cases. The Board *decided that the reply should be that there was no* power under the Midwives Act to carry out that suggestion, and that the Boa [illegible] from Mrs L R C [illegible] to quarantine to [illegible] practice of the Metropolitan [illegible] The report of the standing [illegible] hat Mr. A. G. R. Foulerton, medical officer of health of East Sussex, had attended and discussed with the committee the relations between midwives and medical practitioners, and the best means of preventing "covering." The Board decided that the attention of the Midwives Act Committee should be called to the subject.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

—o—

WEDNESDAY, MAY 26TH.

THE Council resumed its sittings at its offices, 299, Oxford-street, W. Sir DONALD MACALISTER, the President, was in the chair.

Penal Cases.

The Council devoted the whole of the sitting to the hearing of charges brought against medical practitioners.

The first case was that of Robert Kirk, formerly registered as of Delmynden, Carshalton, Surrey, but now of Willington, co. Durham, M.B., Mast. Surg., 1897, Univ. Glasg., who had been summoned to appear before the Council on the following charge, as formulated by its solicitor:—

> That you abused your position as a medical man by committing adultery on various occasions with Laura Sarah Hepple, the wife of Oliver Hepple, when you were professionally attending her and her children, Nellie, Ivy, and Olive Isabel, and that in relation thereto you have been guilty of infamous conduct in a professional respect.

The complainant was Mr. Oliver Hepple, who attended, accompanied by Mr. Hempson, his solicitor.

Dr. KIRK did not answer his notice, nor was he represented.

Mr. HEMPSON made a statement relating to the charge and submitted documentary evidence with a view to show that Dr. Kirk had been in medical attendance on Mr. Hepple's family to a very recent date.

After hearing the evidence of Mr. OLIVER HEPPLE, the Council deliberated on the case *in camerâ.*

The PRESIDENT, addressing Mr. Hempson, said: I have to announce to you that the Council have judged Robert Kirk to have been guilty of infamous conduct in a professional respect, and have directed the Registrar to erase from the Medical Register the name of Robert Kirk.

The Council then considered the case (adjourned from May 27th, 1908) of Christopher Richard Kempster, registered as of Whitehall, Bank Place, Collins street, Melbourne, Mem. R. Coll. Surg. Eng. 1896, Lic. R. Coll. Phys. London 1896, who had been summoned to appear before the Council on the following charge, as formulated by its solicitor:—

> That you l [illegible] chief surgeon [illegible] Melbourne a [illegible] to attract pa [illegible] tisements of [illegible] by a portrait [illegible] that in relation thereto you have been guilty of infamous conduct in a professional respect.

The complainants in this case were the London and Counties Medical Protection Society, Limited, which was represented by its secretary, Dr. Hugh Woods.

Mr. KEMPSTER did not answer to his notice, nor was he represented by counsel or solicitor.

Dr. HUGH WOODS, who conducted the case on behalf of the complainants, submitted to the Council copies of the newspaper containing the advertisement of which complaint was made. The only point in Mr. Kempster's favour was that to some extent he seemed to suggest that he had been drawn into a contract with the institute in question in comparative ignorance of the nature of it, that he did not in any way approve of the advertisements complained of, and that he was withdrawing from it. He (Dr. Woods) had no proof of this except a slight explanation made by Mr. Kempster himself, and unless Mr. Kempster was able to satisfy the Council that he was unaware of the character of the institute when he made the contract, that he dissociated himself from it at the earliest possible moment, and did all in his power to put his position right, he would ask the Council to find him guilty of the charge now made against him.

Mr. WINTERBOTHAM (the solicitor to the Council) said that attention had been drawn to this case by the Medical Board of Victoria. Communications had passed with Mr. Kempster, who stated that when he entered into the contract he had not anticipated that his name would be advertised in the manner it had. He had had difficulties with regard to it. He also had written to say that he had severed his connexion with the institute. However, he had not broken any local regulations. [illegible]

The Council deliberated on the case *in camerâ.*

The PRESIDENT (on the readmission of the public) said: Dr. Woods, I have to announce that the Council has adopted the following resolution:—

> That the Council do now judge Christopher Richard Kempster to have been guilty of infamous conduct in a professional respect, and do direct the Registrar to erase from the Medical Register the name of Christopher Richard Kempster.

The next case to come up for consideration was that of Charles William Brown, registered as of 7, Chorlton-road, Hulme, Manchester, M.B., Mast. Surg. 1889, Univ. Edin., who has been summoned to appear before the Council on the following charge, as formulated by its solicitor:—

> That you have employed as your assistant in connexion with your professional practice a person not duly qualified or registered under the Medical Acts, namely, Mr. Amery, and have knowingly allowed him on your behalf to attend and treat patients in respect of matters requiring professional discretion or skill, and that in relation thereto you have been guilty of infamous conduct in a professional respect.

The complainant was Mr. Thomas George Paterson, who attended and was accompanied by Mr. Alfred Tarbolton of Messrs. Brett, Hamerton, and Tarbolton, solicitors, Manchester.

Mr. Brown appeared in answer to his notice. He was defended by Mr. A. H. Bodkin, counsel, instructed by Mr. W. H. Martin.

Mr. TARBOLTON, who stated the complainant's case, said that the complaint was made by Mr. Paterson, who when called in as a medical man by a family of the name of Simpson in 1908 was told certain facts. These facts gave him the premonition that Mr. Brown was employing an unqualified man, Mr. Amery, for work on which he ought not to employ him. He disclosed these to the chairman of a local division of the British Medical Association, omitting the name, and when the matter was brought before others connected with it they unanimously said that action should be taken.

Mr. BODKIN (intervening): What we have got to do with is not what 12 medical men may have said or done. I would ask Mr. Tarbolton to confine his statement to something relevant to this charge.

Mr. LUSHINGTON (the legal assessor): Mr. Tarbolton, you had better confine yourself to the matter you are trying to prove.

Mr. TARBOLTON went on to say that Mr. Amery was dispenser and bookkeeper to Mr. Brown. He stated that Mr. Amery had for some time paid visits to the house of the Simpsons to attend Miss Jane Simpson, that medicine was called for at Mr. Brown's surgery, and that both Mr. Brown and Mr. Amery had attended Mr. Simpson, the father, on his last illness. He further said that Mr. Brown's account in the case of the father's illness amounted to 17*s.* 6*d.* The customary charge of a medical man in the locality in question was half a crown a visit, and Mr. Brown made five visits. He also referred to a confinement at which Mr. Amery was alleged to have taken a leading part. He also said that he had statutory declarations to show that at operations which Mr. Brown performed Mr. Amery administered the anæsthetic. He was proceeding to refer to the declaration of Mr. E. A. Burgess, M.R.C.S., L.S.A., who had been a locum-tenent for Mr. Brown, when

Mr. BODKIN (intervening) took objection to the declaration on the ground that it was dated as recently as May 18th, 1909, and although he had invited the complainant's solicitor to produce all essential witnesses Mr. Burgess was not present.

Mr. LUSHINGTON ruled that the declaration should be admitted. The Council had no power to compel the attendance of a witness, but when a person who had made a declaration was not put into the witness-box to be cross-examined counsel was allowed a great latitude of criticism.

Mr. TARBOLTON went on to read the declaration of Mr. Burgess, who alleged that during the time when he was locum-tenent for Mr. Brown he found that Mr. Amery was attending to patients.

Mr. THOMAS GEORGE PATERSON was then called as a witness. He said that he was acting from no personal feeling. He spoke on various points touched in the speech of Mr. Tarbolton. The usual fee for a visit and medicine in the district in which the Simpsons lived was 2*s.* 6*d.* 3*s.* 6*d.* was not a usual charge.

Mrs. MARIANNE SIMPSON also gave evidence and stated that Mr. Amery had come to see her daughter. She had considered that he was a qualified medical man and she called him "Dr. Amery." Medicine had been got at Mr. Brown's surgery. Both Mr. Brown and Mr. Amery had gone to see her husband in his last illness. When she paid the bill of 17*s.* 6*d.* she assumed that it was at the rate of 2*s.* 6*d.* a visit.

Cross-examined by Mr. BODKIN, WITNESS admitted that she took no memoranda of how often Mr. Brown came to see her husband in 1907, but she remembered how often he came.

Mr. BODKIN: I suggest to you that from the first time that Mr. Brown saw your husband to the last, he went to your house five times?

WITNESS: He came three times.

Mr. LUSHINGTON: Did Mr. Brown ever give you medicine personally himself?

WITNESS: No, never.

Mr. LUSHINGTON: During the time that Mr. Amery was seeing your daughter's eyes for four years, did you ever get any bill at all from Mr. Brown?

WITNESS: No.

Mr. LUSHINGTON: There was no other account owing to him except in respect of your husband?

WITNESS: No.

Mr. TARBOLTON submitted statutory declarations from other persons in relation to this case.

At the request of Mr. BODKIN the Council assented at this stage to hear the evidence of two medical men from Manchester on behalf of Mr. Brown.

Dr. THOMAS ARTHUR HELME, honorary surgeon to the Northern Hospital, Manchester, examined by Mr. Bodkin, stated that he had practised in Manchester for 20 years, and last year he was chairman of the Lancashire and Cheshire Branch of the British Medical Association. He had known Mr. Brown for a long time. His opinion was that Mr. Brown was a man of the highest standing in the medical profession and never had there been a breath of suspicion against him as a member of it. He went on to say that the charge of 3*s.* 6*d.* was an ordinary one in the district in which Mr. Brown practised.

Dr. ARTHUR WILSON CHAPMAN, J.P., who stated that he was a member of the Manchester city council, said that he had known Mr. Brown about 20 years. Mr. Brown's character and reputation were of the highest. He (Dr. Chapman) got a fee of 3*s.* 6*d.* a visit in the neighbourhood in question. Only this week he had sent one out at the rate of 5*s.* per visit.

The Council adjourned.

THURSDAY, MAY 27TH.

The Council resumed its sittings at its offices, 299, Oxford-street, W. Sir DONALD MACALISTER, the President, was again in the chair.

Bristol University Bill.

The PRESIDENT announced that he had received from the Privy Council a copy of Bristol University Bill, which had passed its second reading in the House of Lords. Clauses 7 and 8 of the Bill affected the Council and he thought that it would be desirable to have them placed on record in the minutes. He moved accordingly.

The motion was agreed to. Clause 7 gives the University power to hold qualifying examinations in medicine, surgery, and midwifery for the purpose of granting a diploma or diplomas conferring the right of registration under the Medical Acts. Clause 8 entitles the council of the University to chose one representative to be a member of the General Medical Council.

Penal Cases.

The Council resumed the hearing of the charge made against Mr. Charles William Brown (consideration of which was adjourned from the previous day).

Several witnesses were examined in support of the charge, and this closed the case against Mr. Brown.

Mr. BODKIN addressed the Council on behalf of Mr. Brown, who, he said, was a gentleman of the highest position and integrity in the medical profession in Manchester. The case had not been sent to the General Medical Council by a branch of the British Medical Association in Manchester, for Dr. Helme, whose position had been explained to the Council on the previous day, denied that it had. The charge was that Mr. Brown had been covering an unqualified assistant. In order that he might deal effectively with that charge counsel said that he must state what he conceived it to be. He supposed that it was unprofessional and improper conduct *for a medical man to spread himself out, as it were*, over a larger area of practice than legitimately fell to him, by the employment of unqualified persons and thereby to enrich himself. If that was the true significance of the offence, then he submitted that there was not a tittle of evidence against Mr. Brown in this case from beginning to end. First let him deal with the case of the Simpsons. It appeared that Mr. Simpson, the father, asked Mrs. Amery, the mother of Mr. Amery, to send her son to see his daughter. He refused to go. Mr. Simpson asked again and Mr. Amery consented. He (Mr. Bodkin) would bring evidence to show that from the first time that Mr. Amery attended Miss Simpson to the last, Mr. Brown had no knowledge of the matter. There was never an entry in any single book of Mr. Brown in regard to the Simpsons except with regard to the last illness of the husband. Mr. Brown never saw Miss Simpson in a professional capacity and never knew that Mr. Amery was attending her. A further charge made against Mr. Brown was that he allowed Mr. Amery to administer anæsthetics. Mr. Amery never administered chloroform or ether, nor had he taken any part at a confinement which it was improper he should take. Counsel also commented on the fact that Mr. Burgess did not appear as a witness and submit himself to cross-examination. There was not a particle of evidence against Mr. Brown and he asked the Council to acquit this gentleman of the charges which had been made against him.

Mr. CHARLES WILLIAM BROWN went into the witness-box and spoke in detail with regard to the matters touched on in his counsel's speech. He had employed Mr. Amery for eight years as dispenser and bookkeeper. He had never allowed Mr. Amery to do work which it was not right for him to do. He had never called at the Simpsons before being called in for the illness of Mr. Simpson. He submitted his books to the Council showing that he had paid five visits on this occasion and his charge for those five visits was 17*s* 6*d*. He did not know that Mr. Amery received anything. He (Mr. Brown) attended the accouchement which had been referred to and carried it out. Mr. Amery might have been present with him, but if there had been any stitching of the patient he (Mr. Brown) would have put it in himself.

Mr. BODKIN: Either in this account of 17*s*. 6*d*. or in any other way have you had 6*d*. for the attendance of Mr. Amery on a patient?

Mr. BROWN: Never in my life.

Mr. TARBOLTON briefly cross-examined the witness.

Mr. LUSHINGTON: When you took Mr. Amery did you know anything *about what examinations he had passed?*

Mr. BROWN: No.

The PRESIDENT: Has he passed any examination while he has been in your service?

Mr. BROWN: No, he has not.

Mr. LUSHINGTON: Did you know he was prescribing in a charitable way?

Mr. BROWN: I did not know until November, 1907.

Do you think it proper that he should prescribe even in a charitable way?—Witness was understood to reply in the negative.

Have you told him not to do so?—Yes.

When did you warn him?—I have discussed it with him.

When?—Since this case arose.

Are you satisfied you have put a stop to it now?—Yes.

Mr. WILLIAM AMERY also gave evidence. Replying to Mr. Bodkin, he said that he was a fourth year's student under the old regulations. He had been employed for some years by Mr. Brown as a dispenser and assistant. He had known the late Mr. Simpson for many years and was on terms of friendship with him. Yielding to the pressure brought to bear on him by his (witness's) mother and Mr. Simpson he agreed to attend the latter's daughter for her eyes.

For about four years you attended Miss Simpson and received money for your visits?—Yes.

Was any entry made in Mr. Brown's books of these visits?—Never.

Did you tell Mr. Brown you had attended her?—I do not think so.

Did he know you were attending her?—I do not think he did.

Did you ever attend Mr. Simpson medically or as a doctor?—No.

Did you go one night to see Mr. Simpson?—I did, and I paid, I think, one or two visits to him.

Was any *charge made for these visits?*—No.

How do you determine the 3*s*. 6*d*. visits?—It does not go by streets. It goes more by the people. It was left to me and I just used my discretion in the matter. He had, he added, never administered chloroform or ether to anyone.

The PRESIDENT having intimated that the case for the defence might close at this point,

The Council deliberated *in camerâ*.

When the public were admitted the PRESIDENT said: M. Charles William Brown, I have to announce to you that the facts alleged against you in the notice of inquiry have not been proved to the satisfaction of the Council. That closes the case.

The Council adjourned.

FRIDAY, MAY 28TH.

The Council resumed its sittings at its offices, 299, Oxford-street. Sir DONALD MACALISTER, the President, was in the chair.

New Member.

An intimation was read from the Victoria University, Manchester, announcing that it had appointed Dr. John Dixon Mann to be a member of the General Medical Council for the term of two years from May 12th, 1909.

Appointment of Committees.

On the motion of Dr. NORMAN MOORE, the nominations of the Branch Councils for the various committees of the Council were adopted as follows:—

Examination Committee.—The English Branch Council: Dr. Taylor, Dr. Saundby, and Dr. Caton. The Scottish Branch Council: Sir Thomas Fraser, Dr. Finlay, and Dr. McVail. The Irish Branch Council: Sir John Moore, Sir Charles Ball, and Dr. Kidd.

Education Committee:—The English Branch Council: Dr. Norman Moore, Sir G. Philipson, and Sir John Williams. The Scottish Branch Council: Dr. Mackay, Mr. Hodsdon, and Dr. Knox. The Irish Branch Council: Sir Thomas Myles, Sir C. Nixon, and Dr. Little.

Public Health Committee:—The English Branch Council: Dr. Cocking, Sir William Power, and Dr. McManus. The Scottish Branch Council: Dr. Norman Walker, Sir John Tuke, and Dr. McVail. The Irish Branch Council: Sir John Moore, Dr. Adye-Curran, and Dr. Kidd.

On the motion of Dr. NORMAN MOORE, the following committees were also appointed:—

Pharmacopœia Committee:—The President (chairman), Dr. Norman Moore, *Dr. Barrs, Sir John Moore, Sir G. Philipson*, Sir Thomas Fraser, Dr. Little, Dr. Caton, and Dr. McVail.

Finance Committee:—Mr. Tomes (chairman), Mr. Morris, Sir John Tuke, and Dr. Little.

Dental Committee:—The President (chairman), Mr. Morris, Mr. Tomes, Mr. Hodsdon, and Sir Thomas Myles.

Dental Education and Examination Committee:—Mr. Tomes (chairman), Mr. Morris, Sir Thomas Myles, Dr. Knox, Sir Charles Ball, and Dr. Finlay.

Students' Registration Committee:—Sir Hugh Beevor (chairman), Dr. Norman Moore, Dr. Adye-Curran, Sir John Batty Tuke, Sir Christopher Nixon, and Dr. Mackay.

The Executive Committee.

The following were elected members of the Executive Committee: Dr. Norman Moore, Sir Hugh Beevor, Mr. Tomes, *Dr. Langley Brown, Sir* John Tuke, Dr. McVail, Sir John Moore, and Sir Charles Ball.

The Penal Cases Committee.

The Penal Cases Committee was elected, and consists of the following members: Dr Saundby, Mr. Tomes, Dr. Finlay, and Sir C. Nixon.

Assistant Examiner in Surgery to the Apothecaries' Society.

On the motion of Sir HUGH BEEVOR, seconded by Mr. MORRIS, it was agreed—

That Mr. H. Stansfield Collier, F.R.C.S. Eng., be appointed assistant examiner in surgery to the Apothecaries' Society of London, vice Mr. McAdam Eccles, who retires by rotation.

Pharmacopœia Committee's Report.

The Pharmacopœia Committee reported to the Council as follows:—
